A data node must have a node ID in the range of 1#49, inclusive. (Management and API nodes may use any integer in the range of 1#63 inclusive as a node ID.)
  - The total maximum number of nodes in a MySQL Cluster is 63. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
  - The maximum number of metadata objects in current versions of MySQL Cluster. This limit is hard-coded. See [Section 19.14.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1”](#), for more information.

## 19.14.3. Limits Relating to Transaction Handling

A number of limitations exist in MySQL Cluster with regard to the handling of transactions. These include the following:

- Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (InnoDB, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) See [Section 19.9.5, “Backup Troubleshooting”](#), for information on how this can affect backing up and restoring Cluster databases.)

### Important

If a `SELECT` from a Cluster table includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency, due to the fact that parts of the values stored in columns of these types are actually read from a separate table.

- **Rollbacks.** There is no partial rollback of transactions. A duplicate key or similar error rolls back the entire transaction.
- **Transactions and memory usage.** As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behaviour of a number of MySQL statements is effected as described in the following list:
  - `TRUNCATE` is not transactional when used on `NDB` tables. If a `TRUNCATE` fails to empty the table, then it must be re-run until it is successful.
  - `DELETE FROM` (even with no `WHERE` clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...` statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use `TRUNCATE` instead.
  - **LOAD DATA statements.** `LOAD DATA INFILE` is not transactional when used on `NDB` tables.

### Important

When executing a `LOAD DATA INFILE` statement, the `NDB` engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

`LOAD DATA FROM MASTER` is not supported in MySQL Cluster.

- **ALTER TABLE and transactions.** When copying an `NDB` table as part of an `ALTER TABLE`, the creation of the copy is non-transactional. (In any case, this operation is rolled back when the copy is deleted.)
- **Transactions and the `COUNT()` function.** When using MySQL Cluster Replication, it is not possible to guarantee the transactional consistency of the `COUNT()` function on the slave. In other words, when performing on the master a series of statements (`INSERT`, `DELETE`, or both) that changes the number of rows in a table within a single transaction, executing `SELECT COUNT(*) FROM table` queries on the slave may yield intermediate results. This is due to the fact that `SELECT COUNT(...)` may perform dirty reads, and is not a bug in the `NDB` storage engine. (See [Bug#31321](#) for more information.)

## 19.14.4. Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 `TEMPORARY FAILURE, DISTRIBUTION CHANGED` and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also [Section 19.14.2, “Limits and Differences from Standard MySQL Limits”](#).

## 19.14.5. Limits Associated with Database Objects

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Identifiers.** Database names, table names and attribute names cannot be as long in `NDB` tables as when using other table handlers. Attribute names are truncated to 31 characters, and if not unique after truncation give rise to errors. Database names and table names can total a maximum of 122 characters. In other words, the maximum length for an `NDB` table name is 122 characters, less the number of characters in the name of the database of which that table is a part.
- **Table names containing special characters.** `NDB` tables whose names contain characters other than letters, numbers, dashes, and underscores and which are created on one SQL node were not always discovered correctly by other SQL nodes. ([Bug#31470](#))

**Note**

This issue was fixed in MySQL 5.1.23, MySQL Cluster NDB 6.2.7, and MySQL Cluster NDB 6.3.4.

- **Number of tables.** The maximum number of [NDB](#) tables is limited to 20320.
- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) per table is limited to 128.
- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** The maximum permitted size of any one row is 8KB. Note that each [BLOB](#) or [TEXT](#) column contributes  $256 + 8 = 264$  bytes towards this total.

## 19.14.6. Unsupported Or Missing Features

A number of features supported by other storage engines are not supported for [NDB](#) tables. Trying to use any of these features in MySQL Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced:

- **Foreign key constraints.** The foreign key construct is ignored, just as it is in [MyISAM](#) tables.
- **OPTIMIZE operations.** [OPTIMIZE](#) operations are not supported.

Beginning with MySQL Cluster NDB 6.3.7, this limitation has been lifted. See [Section 19.14.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1”](#), for more information.

- **LOAD TABLE ... FROM MASTER.** [LOAD TABLE ... FROM MASTER](#) is not supported.
- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in [MyISAM](#).
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See [Section 19.11, “MySQL Cluster Replication”](#), for more information.

**Note**

See [Section 19.14.3, “Limits Relating to Transaction Handling”](#), for more information relating to limitations on transaction handling in [NDB](#).

## 19.14.7. Limitations Relating to Performance

The following performance issues are specific to or especially pronounced in MySQL Cluster:

- **Range scans.** There are query performance issues due to sequential access to the [NDB](#) storage engine; it is also relatively more expensive to do many range scans than it is with either [MyISAM](#) or [InnoDB](#).
- **Reliability of Records in range.** The [Records in range](#) statistic is available but is not completely tested or officially supported. This may result in non-optimal query plans in some cases. If necessary, you can employ [USE INDEX](#) or [FORCE INDEX](#) to alter the execution plan. See [Section 12.2.7.2, “Index Hint Syntax”](#), for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with [USING HASH](#) cannot be used for accessing a table if [NULL](#) is given as part of the key.

## 19.14.8. Issues Exclusive to MySQL Cluster

The following are limitations specific to the [NDBCLUSTER](#) storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.

- **Adding and dropping of data nodes.** Online adding or dropping of data nodes is not currently possible. In such cases, the entire cluster must be restarted.
- **Binary logging.** MySQL Cluster has the following limitations or restrictions with regard to binary logging:
  - `SQL_LOG_BIN` has no effect on data operations; however, it is supported for schema operations.
  - MySQL Cluster cannot produce a binlog for tables having `BLOB` columns but no primary key.
  - Only the following schema operations are logged in a cluster binlog which is *not* on the `mysqld` executing the statement:
    - `CREATE TABLE`
    - `ALTER TABLE`
    - `DROP TABLE`
    - `CREATE DATABASE / CREATE SCHEMA`
    - `DROP DATABASE / DROP SCHEMA`
    - `CREATE TABLESPACE`
    - `ALTER TABLESPACE`
    - `DROP TABLESPACE`
    - `CREATE LOGFILE GROUP`
    - `ALTER LOGFILE GROUP`
    - `DROP LOGFILE GROUP`

See also [Section 19.14.10, “Limitations Relating to Multiple Cluster Nodes”](#).

## 19.14.9. Limitations Relating to Disk Data Storage

- Disk data objects are subject to the following maximums:
  - Maximum number of tablespaces:  $2^{32}$  (4294967296)
  - Maximum number of data files per tablespace:  $2^{16}$  (65535)
  - The theoretical maximum number of extents per tablespace data file is  $2^{16}$  (65525); however, for practical purposes, the recommended maximum number of extents per data file is  $2^8$  (32768).
  - Maximum data file size: The theoretical limit is 64G; however, in MySQL 5.1, the practical upper limit is 32G. This is equivalent to 32768 extents of 1M each.

The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See [Section 12.1.11, “CREATE TABLESPACE Syntax”](#), for more information.

- Use of Disk Data tables is not supported when running the cluster in diskless mode. Beginning with MySQL 5.1.12, it is disallowed altogether. ([Bug#20008](#))

## 19.14.10. Limitations Relating to Multiple Cluster Nodes

**Multiple SQL nodes.** The following are issues relating to the use of multiple MySQL servers as MySQL Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)
- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, MySQL Cluster does not support distributed table locks.)
- **DDL operations.** DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are not safe from data node failures. If a

data node fails while trying to perform one of these, the data dictionary is locked and no further DDL statements can be executed without restarting the cluster.

**Multiple management nodes.** When using multiple management servers:

- You must give nodes explicit IDs in connectstrings because automatic allocation of node IDs does not work across multiple management servers.
- You must take extreme care to have the same configurations for all management servers. No special checks for this are performed by the cluster.

**Multiple data node processes.** While it is possible to run multiple cluster processes concurrently on a single host, it is not always advisable to do so for reasons of performance and high availability, as well as other considerations. In particular, in MySQL 5.1 and MySQL Cluster NDB 6.x, we do not support for production use any MySQL Cluster deployment in which more than one `ndbd` process is run on a single physical machine.

#### Note

We may support multiple data nodes per host in a future MySQL release, following additional testing. However, in current versions of MySQL Cluster, such configurations can be considered experimental only.

**Multiple network addresses.** Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

#### Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See [Section 19.3.4.7, “Cluster TCP/IP Connections”](#), for more information.

## 19.14.11. Previous MySQL Cluster Issues Resolved in MySQL 5.1

A number of limitations and related issues existing in earlier versions of MySQL Cluster have been resolved:

- **Variable-length column support.** The `NDBCLUSTER` storage engine now supports variable-length column types for in-memory tables.

Previously, for example, any Cluster table having one or more `VARCHAR` fields which contained only relatively small values, much more memory and disk space were required when using the `NDBCLUSTER` storage engine than would have been the case for the same table and data using the `MYISAM` engine. In other words, in the case of a `VARCHAR` column, such a column required the same amount of storage as a `CHAR` column of the same size. In MySQL 5.1, this is no longer the case for in-memory tables, where storage requirements for variable-length column types such as `VARCHAR` and `BINARY` are comparable to those for these column types when used in `MYISAM` tables (see [Section 10.5, “Data Type Storage Requirements”](#)).

#### Important

For MySQL Cluster Disk Data tables, the fixed-width limitation continues to apply. See [Section 19.12, “MySQL Cluster Disk Data Tables”](#).

- **Replication with MySQL Cluster.** It is now possible to use MySQL replication with Cluster databases. For details, see [Section 19.11, “MySQL Cluster Replication”](#).

**Circular Replication.** Circular replication is supported for MySQL Cluster beginning with MySQL 5.1.18. See [Section 19.11.3, “Known Issues in MySQL Cluster Replication”](#).

- **auto\_increment\_increment and auto\_increment\_offset.** The `auto_increment_increment` and `auto_increment_offset` server system variables are supported for Cluster replication beginning with MySQL 5.1.20.

- **Database autodiscovery and online schema changes.** Autodiscovery of databases is now supported for multiple MySQL servers accessing the same MySQL Cluster, provided that a given `mysqld` is already running and is connected to the cluster at the time that the database is created on a different `mysqld`.

What this means is that if a `mysqld` process first connects to the cluster after a database named `db_name` has been created,

you should issue a `CREATE SCHEMA db_name` statement on the “new” MySQL server when it first accesses that MySQL Cluster. Once this has been done, the “new” `mysqld` should be able to detect any tables in that database tables without errors.

This also means that online schema changes in NDB tables are now possible. That is, the result of operations such as `ALTER TABLE` and `CREATE INDEX` performed on one SQL node in the cluster are now visible to the cluster's other SQL nodes without any additional action being taken.

- **Backup and restore between architectures.** Beginning with MySQL 5.1.10, it is possible to perform a Cluster backup and restore between different architectures. Previously — for example — you could not back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. (Bug#19255)
- **Character set directory.** Beginning with MySQL 5.1.10, it is possible to install MySQL with Cluster support to a non-default location and change the search path for font description files using either the `--basedir` or `--character-sets-dir` options. (Previously, `ndbd` in MySQL 5.1 searched only the default path — typically `/usr/local/mysql/share/mysql/charsets` — for character sets.)
- In MySQL 5.1, it is no longer necessary, when running multiple management servers, to restart all the cluster's data nodes to enable the management nodes to see one another.
- **Length of `CREATE TABLE` statements.** `CREATE TABLE` statements may be no more than 4096 characters in length. *This limitation affects MySQL 5.1.6, 5.1.7, and 5.1.8 only.* (See Bug#17813)
- **IGNORE and REPLACE functionality.** In MySQL 5.1.7 and earlier, `INSERT IGNORE`, `UPDATE IGNORE`, and `REPLACE` were supported only for primary keys, but not for unique keys. It was possible to work around this issue by removing the constraint, then dropping the unique index, performing any inserts, and then adding the unique index again.

This limitation was removed for `INSERT IGNORE` and `REPLACE` in MySQL 5.1.8. (See Bug#17431.)

- **AUTO\_INCREMENT columns.** In MySQL 5.1.10 and earlier versions, the maximum number of tables having `AUTO_INCREMENT` columns — including those belonging to hidden primary keys — was 2048.

This limitation was lifted in MySQL 5.1.11.

- **Maximum number of cluster nodes.** Prior to MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster was 63, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

Starting with MySQL Cluster NDB 6.1.1, up to 255 API nodes (including MySQL servers acting as cluster SQL nodes) are supported by a single cluster. The total number of data nodes and management nodes beginning with this version is 63, of which up to 48 can be data nodes.

### Note

The limitation that a data node cannot have a node ID greater than 49 continues to apply.

- **Recovery of memory from deleted rows.** Beginning with MySQL Cluster NDB 6.3.7, memory can be reclaimed from an NDB table for reuse with any NDB table by employing `OPTIMIZE TABLE`, subject to the following limitations:
  - Only in-memory tables are supported; the `OPTIMIZE TABLE` statement still has no effect on MySQL Cluster Disk Data tables.
  - Only variable-length columns (such as those declared as `VARCHAR`, `TEXT`, or `BLOB`) are supported.

However, you can force columns defined using fixed-length data types (such as `CHAR`) to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

See Section 12.1.10, “`CREATE TABLE Syntax`”, and Section 12.1.4, “`ALTER TABLE Syntax`”, for information on these options.

You can regulate the effects of `OPTIMIZE` on performance by adjusting the value of the global system variable `ndb_optimization_delay`, which sets the number of milliseconds to wait between batches of rows being processed by `OPTIMIZE`. The default value is 10 milliseconds. It is possible to set a lower value (to a minimum of 0), but not recommended. The maximum is 100000 milliseconds (that is, 100 seconds).

## 19.15. MySQL Cluster Development Roadmap

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.1 and MySQL Cluster NDB as compared to MySQL 5.0.

There are a number of significant changes in the implementation of the `NDBCLUSTER` storage engine in mainline MySQL 5.1 re-

leases up to and including MySQL 5.1.23 as compared to that in MySQL 5.0; MySQL Cluster NDB makes further changes and improvements in MySQL Cluster in addition to these. The changes and features most likely to be of interest are shown in the following table:

| <b>MySQL 5.1 (through 5.1.23)</b>                                                                          |
|------------------------------------------------------------------------------------------------------------|
| MySQL Cluster Replication                                                                                  |
| Disk Data storage                                                                                          |
| Variable-size columns                                                                                      |
| User-defined partitioning                                                                                  |
| Autodiscovery of table schema changes                                                                      |
| Online adding and dropping of indexes                                                                      |
| <b>MySQL Cluster NDB 6.1</b>                                                                               |
| Greater number of cluster nodes                                                                            |
| Disabling of arbitration                                                                                   |
| Additional <code>DUMP</code> commands                                                                      |
| Faster Disk Data backups                                                                                   |
| Batched slave updates                                                                                      |
| <b>MySQL Cluster NDB 6.2</b>                                                                               |
| Improved backup status reporting ( <code>BackupReportFrequency</code> , <code>REPORT BackupStatus</code> ) |
| Multiple connections per SQL node                                                                          |
| Data access with <code>NdbRecord</code> (NDB API)                                                          |
| <code>REPORT MemoryUsage</code> command                                                                    |
| Memory allocation improvements                                                                             |
| Management client connection control                                                                       |
| Micro-GCPs                                                                                                 |
| Online <code>ADD COLUMN</code> ; improved online index creation                                            |
| <b>MySQL Cluster NDB 6.3</b>                                                                               |
| Conflict detection and resolution for multi-master replication                                             |
| Compressed backups and local checkpoints                                                                   |
| Support for <code>OPTIMIZE TABLE</code>                                                                    |
| Parallel data node recovery                                                                                |
| Enhanced transaction coordinator selection                                                                 |
| Improved SQL statement performance metrics                                                                 |
| Transaction batching                                                                                       |
| <code>ndb_restore</code> attribute promotion                                                               |
| Support for <code>epoll</code> (Linux only)                                                                |
| Distribution awareness                                                                                     |
| NDB thread locks; realtime extensions for multiple CPUs                                                    |

### 19.15.1. Features Added in MySQL 5.1 Cluster

A number of new features for MySQL Cluster have been implemented in MySQL 5.1 through MySQL 5.1.23, when support for MySQL Cluster was moved to MySQL Cluster NDB. All of the features in the following list are also available in all MySQL Cluster NDB (6.1 and later) releases.

- **Integration of MySQL Cluster into MySQL Replication.** MySQL Cluster Replication makes it possible to replicate from one MySQL Cluster to another. Updates on any SQL node (MySQL server) in the cluster acting as the master are replicated to the slave cluster; the state of the slave side remains consistent with the cluster acting as the master. This is sometimes referred

to as *asynchronous replication* between clusters, providing *geographic redundancy*. It is also possible to replicate from a MySQL Cluster acting as the master to a standalone MySQL server acting as the slave, or from a standalone MySQL master server to a slave cluster; in either of these cases, the standalone MySQL server uses a storage engine other than `NDB-CLUSTER`. Multi-master replication setups such as circular replication are also supported.

See [Section 19.11, “MySQL Cluster Replication”](#).

- **Support for storage of rows on disk.** Storage of `NDBCLUSTER` table data on disk is now supported. Indexed columns, including the primary key hash index, must still be stored in RAM; however, all other columns can be stored on disk.

See [Section 19.12, “MySQL Cluster Disk Data Tables”](#).

- **Variable-size columns.** In MySQL 5.0, an `NDBCLUSTER` table column defined as `VARCHAR(255)` used 260 bytes of storage independent of what was stored in any particular record. In MySQL 5.1 Cluster tables, only the portion of the column actually taken up by the record is stored. This makes possible a significant reduction in space requirements for such columns as compared to previous release series — by a factor of up to 5 in many cases.
- **User-defined partitioning.** Users can define partitions based on columns that are part of the primary key. It is possible to partition `NDB` tables based on `KEY` and `LINEAR KEY` schemes. This feature is also available for many other MySQL storage engines, which support additional partitioning types that are not available with `NDBCLUSTER` tables.

For additional general information about user-defined partitioning in MySQL 5.1, see [Chapter 20, \*Partitioning\*](#). Specifics of partitioning types are discussed in [Section 20.2, “Partition Types”](#).

The MySQL Server can also determine whether it is possible to “prune away” some of the partitions from the `WHERE` clause, which can greatly speed up some queries. See [Section 20.4, “Partition Pruning”](#), for information about designing tables and queries to take advantage of partition pruning.

- **Autodiscovery of table schema changes.** In MySQL 5.0, it was necessary to issue a `FLUSH TABLES` statement or a “dummy” `SELECT` in order for new `NDBCLUSTER` tables or changes made to schemas of existing `NDBCLUSTER` tables on one SQL node to be visible on the cluster’s other SQL nodes. In MySQL 5.1, this is no longer necessary; new Cluster tables and changes in the definitions of existing `NDBCLUSTER` tables made on one SQL node are immediately visible to all SQL nodes connected to the cluster.

#### Note

When creating a new database, it is still necessary in MySQL 5.1 to issue a `CREATE DATABASE` or `CREATE SCHEMA` statement on each SQL node in the cluster.

- **Distribution awareness (NDB API).** *Distribution awareness* is a mechanism by which the best data node is automatically selected to be queried for information. (Conceptually, it is similar in some ways to partition pruning (see [Section 20.4, “Partition Pruning”](#)). To take advantage of distribution awareness, you should do the following:
  1. Determine which table column is most likely to be used for finding matching records.
  2. Make this column part of the table’s primary key.
  3. Explicitly partition the table by `KEY`, using this column as the table’s partitioning key.
 Following these steps causes records with the same value for the partitioning column to be stored on the same partition (that is, in the same node group). When reading data, transactions are begun on the data node actually having the desired rows instead of this node being determined by the usual round-robin mechanism.

#### Important

In order to see a measureable impact on performance, the cluster must have at least four data nodes, since, with only two data nodes, both data nodes have exactly the same data.

Using distribution awareness can yield performance increase of as great as 45% when using four data nodes, and possibly more when using a greater number of data nodes.

#### Note

In mainline MySQL 5.1 releases, distribution awareness was supported only when using the NDB API; support was added for SQL and API nodes in MySQL Cluster NDB 6.3 (see [Section 19.15.4, “Features Added in MySQL Cluster NDB 6.3”](#), which includes an example showing how to create a table in order to take advantage of distribution awareness).

See [Section 19.14.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1”](#), for more information.

## 19.15.2. Features Added in MySQL Cluster NDB 6.1

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.1. All of the changes in this list are also available in MySQL Cluster NDB 6.2 and 6.3 releases. For detailed information about all changes made in MySQL Cluster NDB 6.1, see [Section 19.17.3, “Changes in MySQL Cluster NDB 6.1”](#).

- **Increased number of cluster nodes.** The maximum number of all nodes in a MySQL Cluster has been increased to 255. For more information, see [Section 19.14.10, “Limitations Relating to Multiple Cluster Nodes”](#).
- **Disabling arbitration.** It is now possible to disable arbitration by setting `ArbitrationRank=0` on all cluster management and SQL nodes. For more information, see [Defining the Management Server: `ArbitrationRank`](#) and [Defining SQL and Other API Nodes: `ArbitrationRank`](#).
- **Additional DUMP commands.** New management client `DUMP` commands provide help with tracking transactions, scan operations, and locks. See [Section 19.7.2, “Commands in the MySQL Cluster Management Client”](#), and [DUMP Commands](#), for more information.
- **Faster Disk Data backups.** Improvements in backups of Disk Data tables can yield a 10 to 15% increase in backup speed of Disk Data tables.
- **Batched slave updates.** Batching of updates on cluster replication slaves, enabled using the `--slave-allow-batching` option for `mysqld`, increases replication efficiency. For more information, see [Section 19.11.6, “Starting Replication \(Single Replication Channel\)”](#).

### 19.15.3. Features Added in MySQL Cluster NDB 6.2

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.2. All of the changes in this list are also available in MySQL Cluster NDB 6.3. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 6.2, see [Section 19.17.2, “Changes in MySQL Cluster NDB 6.2”](#).

- **Enhanced backup status reporting.** Backup status reporting has been improved, aided in part by the introduction of a `BackupReportFrequency` configuration parameter; see [Defining Data Nodes: `BackupReportFrequency`](#), for more information.
- **Multiple cluster connections per SQL node.** A single MySQL server acting as a MySQL Cluster SQL node can employ multiple connections to the cluster using the `--ndb-cluster-connection-pool` startup option for `mysqld`. This option is described in [MySQL Cluster-Related Command Options for `mysqld`: `--ndb-cluster-connection-pool` option](#).
- **New data access interface.** The `NdbRecord` interface provides a new and simplified data handler for use in NDB API applications. See [The `NdbRecord` Interface](#), for more information.
- **New reporting commands.** The new management client `REPORT BackupStatus` and `REPORT MemoryUsage` commands provide better access to information about the status of MySQL Cluster backups and how much memory is being used by MySQL Cluster for data and index storage. See [Section 19.7.2, “Commands in the MySQL Cluster Management Client”](#), for more information about the `REPORT` commands. In addition, in-progress status reporting is provided by the `ndb_restore` utility; see [Section 19.9.3, “`ndb\_restore` — Restore a Cluster Backup”](#).
- **Improved memory allocation and configuration.** Memory is now allocated by the NDB kernel to tables on a page-by-page basis, which significantly reduces the memory overhead required for maintaining `NDBCLUSTER` tables. In addition, the `MaxAllocate` configuration parameter now makes it possible to set the maximum size of the allocation unit used for table memory; for more information about this configuration parameter, see [Defining Data Nodes: `MaxAllocate`](#).
- **Choice of fixed-width or variable-width columns.** You can control whether fixed-width or variable-width storage is used for a given column of an NDB table by employing of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. In addition, the ability to control whether a given column of an NDB table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. For more information, see [Section 12.1.10, “`CREATE TABLE` Syntax”](#), and [Section 12.1.4, “`ALTER TABLE` Syntax”](#).
- **Controlling management client connections.** The `--bind-address` cluster management server startup option makes it possible to restrict management client connections to `ndb_mgmd` to a single host (IP address or hostname) and port, which can make MySQL Cluster management operations more secure. For more information about this option, see [Section 19.6.5.2, “Command Options for `ndb\_mgmd`”](#).
- **Micro-GCPs.** Due to a change in the protocol for handling of global checkpoints (GCPs handled in this manner sometimes being referred to as “micro-GCPs”), it is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` configuration parameter. This improves the reliability and performance of MySQL Cluster Replication. For more information, see [Defining Data Nodes: `TimeBetweenEpochs`](#) and [Defining Data Nodes: `TimeBetweenEpochsTimeout`](#).

- **Core online schema change support.** Support for the online `ALTER TABLE` operations `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` is available. When the `ONLINE` keyword is used, the `ALTER TABLE` is non-copying, which means that indexes do not have to be re-created, which provides these benefits:
  - Single user mode is no longer required for `ALTER TABLE` operations that can be performed online.
  - Transactions can continue during `ALTER TABLE` operations that can be performed online.
  - Tables being altered online are not locked.
 Online `CREATE INDEX` and `DROP INDEX` statements are also supported. Online changes can be suppressed using the `OFFLINE` key word. See [Section 12.1.4, “ALTER TABLE Syntax”](#), [Section 12.1.7, “CREATE INDEX Syntax”](#), and [Section 12.1.13, “DROP INDEX Syntax”](#), for more detailed information.
- **mysql.ndb\_binlog\_index improvements.** More information has been added to the `mysql.ndb_binlog_index` table so that it is possible to determine which originating epochs have been applied inside an epoch. This is particularly useful for 3-way replication. See [Section 19.11.4, “Cluster Replication Schema and Tables”](#), for more information.
- **Epoch lag control.** The `MaxBufferedEpochs` data node configuration parameter provides a means to control the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect. For a discussion of this configuration parameter, see [Defining Data Nodes: MaxBufferedEpochs](#).

## 19.15.4. Features Added in MySQL Cluster NDB 6.3

The following list provides an overview of significant feature additions and changes first made in MySQL Cluster NDB 6.3. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 6.3, see [Section 19.17.1, “Changes in MySQL Cluster NDB 6.3”](#).

- **Conflict detection and resolution.** It is now possible to detect and resolve conflicts that arise in multi-master replication scenarios, such as circular replication, when different masters may try to update the same row on the slave with different data. Both “greatest timestamp wins” and “same timestamp wins” scenarios are supported. For more information, see [Section 19.11.10, “MySQL Cluster Replication Conflict Resolution”](#).
- **Recovery of “one master, many slaves” replication setups.** Recovery of multi-way replication setups (“one master, many slaves”) is now supported via the `--ndb-log-orig` server option and changes in the `mysql.ndb_binlog_index` table. See [Section 19.11.4, “Cluster Replication Schema and Tables”](#), for more information.
- **Enhanced selection options for transaction coordinator.** New values and behaviors are introduced for `--ndb_optimized_node_selection` allowing for greater flexibility when an SQL node chooses a transaction coordinator. See [MySQL Cluster System Variables: ndb\\_optimized\\_node\\_selection](#), for more information.
- **Replication heartbeats.** Replication heartbeats facilitate the task of monitoring and detecting failures in master-slave connections in real time. This feature is implemented via a new `MASTER_HEARTBEAT_PERIOD = value` clause for the `CHANGE MASTER TO` statement and the addition of two status variables `Slave_heartbeat_period` and `Slave_received_heartbeats`. For more information, see [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#).
- **NDB thread locks.** It is possible to lock NDB execution threads and maintenance threads (such as filesystem and other operating system threads) to specific CPUs on multiprocessor data node hosts, and to leverage real-time scheduling.
- **Improved performance of updates using primary keys or unique keys.** The number of unnecessary reads when performing a primary key or unique key update has been greatly reduced. Since it is seldom necessary to read a record prior to an update, this can yield a considerable improvement in performance. In addition, primary key columns are no longer written to when not needed during update operations.
- **Batching improvements.** Support of batched `DELETE` and `UPDATE` operations has been significantly improved. Batching of `UPDATE WHERE . . .` and multiple `DELETE` operations is also now implemented.
- **Improved SQL statement performance metrics.** The `Ndb_execute_count` system status variable measures the number of round trips made by SQL statements to the NDB kernel, providing an improved metric for determining efficiency with which statements are executed. For more information, see [MySQL Cluster Status Variables: Ndb\\_execute\\_count](#).
- **Compressed LCPs and backups.** Compressed local checkpoints and backups can save 50% or more of the disk space used by uncompressed LCPs and backups. These can be enabled using the two new data node configuration parameters `CompressedLCP` and `CompressedBackup`, respectively. See [MySQL Cluster Status Variables: CompressedBackup](#), and [MySQL Cluster Status Variables: CompressedLCP](#), for more information about these parameters.
- **OPTIMIZE TABLE support with NDBCLUSTER tables.** `OPTIMIZE TABLE` is supported for dynamic columns of in-memory NDB tables. In such cases, it is no longer necessary to drop (and possibly to re-create) a table, or to perform a rolling

restart, in order to recover memory from deleted rows for general re-use by Cluster. The performance of `OPTIMIZE` on Cluster tables can be tuned by adjusting the value of the `ndb_optimization_delay` system variable, which controls the number of milliseconds to wait between processing batches of rows by `OPTIMIZE TABLE`. In addition, `OPTIMIZE TABLE` on an `NDBCLUSTER` table can be interrupted by, for example, killing the SQL thread performing the `OPTIMIZE` operation.

- **Batching of transactions.** It is possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` to `1` or `ON`. To use this feature, `AUTOCOMMIT` must be set to `0` or `OFF`. Batch sizes can be controlled using the `--ndb-batch-size` option for `mysqld`. For more information, see [Section 19.4.2, “MySQL Cluster-Related Command Options for `mysqld`”](#), and [Section 19.4.3, “MySQL Cluster System Variables”](#).
- **Attribute promotion with `ndb_restore`.** It is possible using `ndb_restore` to restore data reliably from a column of a given type to a column that uses a “larger” type. This is sometimes referred to as *attribute promotion*. For example, MySQL Cluster backup data that originated in a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column. See [Section 19.9.3, “`ndb\_restore` — Restore a Cluster Backup”](#), for more information.
- **Parallel data node recovery.** Recovery of multiple data nodes can now be done in parallel, rather than sequentially. In other words, several data nodes can be restored concurrently, which can often result in much faster recovery times than when they are restored one at a time.
- **Increased local checkpoint efficiency.** Only 2 local checkpoints are stored, rather than 3, lowering disk space requirements and the size and number of redo log files.
- **`NDBCLUSTER` table persistence control.** Persistence of `NDB` tables can be controlled using the session variables `ndb_table_temporary` and `ndb_table_no_logging`. `ndb_table_no_logging` causes `NDB` tables not to be checkpointed to disk; `ndb_table_temporary` does the same, and in addition, no schema files are created. See [Section 19.4.1, “MySQL Cluster Server Option and Variable Reference”](#).
- **Epoll support (*Linux only*).** *Epoll* is an improved method for handling file descriptors, which is more efficient than scanning to determine whether a file descriptor has data to be read. (The term *epoll* is specific to Linux and equivalent functionality is known by other names on other platforms such as Solaris and FreeBSD.) Currently, MySQL Cluster supports this functionality on Linux only.
- **Distribution awareness (SQL nodes).** In MySQL Cluster `NDB 6.3`, SQL nodes can take advantage of [distribution awareness](#). Here we provide a brief example showing how to design a table to make a given class of queries distribution-aware. Suppose an `NDBCLUSTER` table `t1` has the following schema:

```
CREATE TABLE t1 (
 userid INT NOT NULL,
 serviceid INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 data VARCHAR(255)
) ENGINE=NDBCLUSTER;
```

Suppose further that most of the queries to be used in our application test values of the `userid` column of this table. The form of such a query looks something like this:

```
SELECT columns FROM t1
WHERE userid relation value;
```

In this query, `relation` represents some relational operator, such as `=`, `<`, `>`, and so on. Queries using `IN` and a list of values can also be used:

```
SELECT columns FROM t1
WHERE userid IN value_list;
```

In order to make use of distribution awareness, we need to make the `userid` column part of the table's primary key, then explicitly partition the table with this column being used as the partitioning key. (Recall that for a partitioned table having one or more unique keys, all columns of the table's partitioning key must also be part of all of the unique keys — for more information and examples, see [Section 20.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#).) In other words, the table schema should be equivalent to the following `CREATE TABLE` statement:

```
CREATE TABLE t1 (
 userid INT NOT NULL,
 serviceid INT NOT NULL AUTO_INCREMENT,
 data VARCHAR(255),
 PRIMARY KEY p (userid,serviceid)
) ENGINE=NDBCLUSTER
PARTITION BY KEY(userid);
```

When the table is partitioned in this way, all rows having the same `userid` value are found on the same node group, and the MySQL Server can immediately select the optimal node to use as the transaction coordinator.

- **Realtime extensions for multiple CPUs.** When running MySQL Cluster data nodes on hosts with multiple processors, the realtime extensions make it possible to give priority to the data node process and control on which CPU cores it should operate. This can be done using the data node configuration parameters `RealtimeScheduler`, `SchedulerExecutionTimer` and `SchedulerSpinTimer`. Doing so properly can significantly lower response times and make them much more predict-

able response. For more information about using these parameters, see [Defining Data Nodes: Realtime Performance Parameters](#)

## 19.16. MySQL Cluster Glossary

The following terms are useful to an understanding of MySQL Cluster or have specialized meanings when used in relation to it.

- **Cluster.** In its generic sense, a cluster is a set of computers functioning as a unit and working together to accomplish a single task.
  - **NDBCLUSTER.** This is the storage engine used in MySQL to implement data storage, retrieval, and management distributed among several computers.
  - **MySQL Cluster.** This refers to a group of computers working together using the [NDB](#) storage engine to support a distributed MySQL database in a *shared-nothing architecture* using *in-memory storage*.
- **Configuration files.** Text files containing directives and information regarding the cluster, its hosts, and its nodes. These are read by the cluster's management nodes when the cluster is started. See [Section 19.3.4, “Configuration File”](#), for details.
- **Backup.** A complete copy of all cluster data, transactions and logs, saved to disk or other long-term storage.
- **Restore.** Returning the cluster to a previous state, as stored in a backup.
- **Checkpoint.** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to Cluster, it is a point in time where all committed transactions are stored on disk. With regard to the [NDB](#) storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained:
  - **Local Checkpoint (LCP).** This is a checkpoint that is specific to a single node; however, LCP's take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.
  - **Global Checkpoint (GCP).** A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.
- **Cluster host.** A computer making up part of a MySQL Cluster. A cluster has both a *physical* structure and a *logical* structure. Physically, the cluster consists of a number of computers, known as *cluster hosts* (or more simply as *hosts*. See also **Node** and **Node group** below.
- **Node.** This refers to a logical or functional unit of MySQL Cluster, and is sometimes also referred to as a *cluster node*. In the context of MySQL Cluster, we use the term “node” to indicate a *process* rather than a physical component of the cluster. There are three node types required to implement a working MySQL Cluster:
  - **Management nodes.** Manages the other nodes within the MySQL Cluster. It provides configuration data to the other nodes; starts and stops nodes; handles network partitioning; creates backups and restores from them, and so forth.
  - **SQL nodes.** Instances of MySQL Server which serve as front ends to data kept in the cluster's **data nodes**. Clients desiring to store, retrieve, or update data can access an SQL node just as they would any other MySQL Server, employing the usual MySQL authentication methods and APIs; the underlying distribution of data between node groups is transparent to users and applications. SQL nodes access the cluster's databases as a whole without regard to the data's distribution across different data nodes or cluster hosts.
  - **Data nodes.** These nodes store the actual data. Table data fragments are stored in a set of node groups; each node group stores a different subset of the table data. Each of the nodes making up a node group stores a replica of the fragment for which that node group is responsible. Currently, a single cluster can support up to 48 data nodes total.

It is possible for more than one node to co-exist on a single machine. (In fact, it is even possible to set up a complete cluster on one machine, although one would almost certainly *not* want to do this in a production environment.) It may be helpful to remember that, when working with MySQL Cluster, the term *host* refers to a physical component of the cluster whereas a *node* is a logical or functional component (that is, a process).

**Note Regarding Terms.** In older versions of the MySQL Cluster documentation, data nodes were sometimes referred to as “database nodes”. The term “storage nodes” has also been used. In addition, SQL nodes were sometimes known as “client nodes”. This older terminology has been deprecated to minimize confusion, and for this reason should be avoided. They are also often referred to as “API nodes” — an SQL node is actually an API node that provides an SQL interface to the cluster.

- **Node group.** A set of data nodes. All data nodes in a node group contain the same data (fragments), and all nodes in a single group should reside on different hosts. It is possible to control which nodes belong to which node groups.

For more information, see [Section 19.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

- **Node failure.** MySQL Cluster is not solely dependent upon the functioning of any single node making up the cluster; the cluster can continue to run if one or more nodes fail. The precise number of node failures that a given cluster can tolerate depends upon the number of nodes and the cluster's configuration.
- **Node restart.** The process of restarting a failed cluster node.
- **Initial node restart.** The process of starting a cluster node with its filesystem removed. This is sometimes used in the course of software upgrades and in other special circumstances.
- **System crash (or system failure).** This can occur when so many cluster nodes have failed that the cluster's state can no longer be guaranteed.
- **System restart.** The process of restarting the cluster and reinitializing its state from disk logs and checkpoints. This is required after either a planned or an unplanned shutdown of the cluster.
- **Fragment.** A portion of a database table; in the **NDB** storage engine, a table is broken up into and stored as a number of fragments. A fragment is sometimes also called a “partition”; however, “fragment” is the preferred term. Tables are fragmented in MySQL Cluster in order to facilitate load balancing between machines and nodes.
- **Replica.** Under the **NDB** storage engine, each table fragment has number of replicas stored on other data nodes in order to provide redundancy. Currently, there may be up four replicas per fragment.
- **Transporter.** A protocol providing data transfer between nodes. MySQL Cluster currently supports four different types of transporter connections:
  - **TCP/IP.** This is, of course, the familiar network protocol that underlies HTTP, FTP (and so on) on the Internet. TCP/IP can be used for both local and remote connections.
  - **SCI.** Scalable Coherent Interface is a high-speed protocol used in building multiprocessor systems and parallel-processing applications. Use of SCI with MySQL Cluster requires specialized hardware, as discussed in [Section 19.13.1, “Configuring MySQL Cluster to use SCI Sockets”](#). For a basic introduction to SCI, see [this essay at dolphins.com](#).
  - **SHM.** Unix-style **shared memory** segments. Where supported, SHM is used automatically to connect nodes running on the same host. The [Unix man page for shmop\(2\)](#) is a good place to begin obtaining additional information about this topic.

### Note

The cluster transporter is internal to the cluster. Applications using MySQL Cluster communicate with SQL nodes just as they do with any other version of MySQL Server (via TCP/IP, or through the use of Unix socket files or Windows named pipes). Queries can be sent and results retrieved using the standard MySQL client APIs.

- **NDB.** This stands for **Network Database**, and refers to the storage engine used to enable MySQL Cluster. The **NDB** storage engine supports all the usual MySQL data types and SQL statements, and is **ACID**-compliant. This engine also provides full support for transactions (commits and rollbacks).
- **Shared-nothing architecture.** The ideal architecture for a MySQL Cluster. In a true shared-nothing setup, each node runs on a separate host. The advantage such an arrangement is that there no single host or node can act as single point of failure or as a performance bottle neck for the system as a whole.
- **In-memory storage.** All data stored in each data node is kept in memory on the node's host computer. For each data node in the cluster, you must have available an amount of RAM equal to the size of the database times the number of replicas, divided by the number of data nodes. Thus, if the database takes up 1GB of memory, and you want to set up the cluster with four replicas and eight data nodes, a minimum of 500MB memory will be required per node. Note that this is in addition to any requirements for the operating system and any other applications that might be running on the host.

In MySQL 5.1, it is also possible to create *Disk Data* tables where non-indexed columns are stored on disk, thus reducing the memory footprint required by the cluster. Note that indexes and indexed column data are still stored in RAM. See [Section 19.12, “MySQL Cluster Disk Data Tables”](#).

- **Table.** As is usual in the context of a relational database, the term “table” denotes a set of identically structured records. In MySQL Cluster, a database table is stored in a data node as a set of fragments, each of which is replicated on additional data nodes. The set of data nodes replicating the same fragment or set of fragments is referred to as a *node group*.
- **Cluster programs.** These are command-line programs used in running, configuring, and administering MySQL Cluster. They include both server daemons:
  - `ndbd`:

The data node daemon (runs a data node process)

- `ndb_mgmd`:

The management server daemon (runs a management server process)

and client programs:

- `ndb_mgm`:

The management client (provides an interface for executing management commands)

- `ndb_waiter`:

Used to verify status of all nodes in a cluster

- `ndb_restore`:

Restores cluster data from backup

For more about these programs and their uses, see [Section 19.6, “Process Management in MySQL Cluster”](#).

- **Event log.** MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 19.7.3, “Event Reports Generated in MySQL Cluster”](#). Event logs are of two types:
  - **Cluster log.** Keeps a record of all desired reportable events for the cluster as a whole.
  - **Node log.** A separate log which is also kept for each individual node.

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

- **Angel process.** When a data node is started, `ndbd` actually starts two processes. One of these is known as the “angel” process; its purpose is to check to make sure that the main `ndbd` process continues to run, and to restart the main process if it should stop for any reason.
- **Watchdog thread.** Each `ndbd` process has an internal *watchdog thread* which monitors the main worker thread, ensuring forward progress and a timely response to cluster protocols such as the cluster heartbeat. If the `ndbd` process is not being woken up promptly by the operating system when its sleep time expires, `INFO` and `WARNING` events, which are identifiable because they contain “Watchdog:...”, are written to the cluster log. Such messages are usually a symptom of an overloaded system; you should see what else is running on the system, and whether the `ndbd` process is being swapped out to disk. If `ndbd` cannot wake up regularly then it cannot respond to heartbeat messages on time, and other nodes eventually consider it “dead” due to the missed heartbeats, causing it to be excluded from the cluster.

## 19.17. Changes in MySQL Cluster 6.x

This section contains changelog information for MySQL Cluster that use version 6.1, 6.2, and 6.3 of the `NDBCLUSTER` storage engine.

Each MySQL Cluster release is based on a mainline MySQL 5.1 release and a particular version of the `NDBCLUSTER` storage engine, as shown in the version string returned by executing `SELECT VERSION()` in the `mysql` client, or by executing the `ndb_mgm` client `SHOW` or `STATUS` command; for more information, see [Chapter 19, MySQL Cluster](#).

For general information about features added in MySQL Cluster, see [Section 19.15, “MySQL Cluster Development Roadmap”](#). For a complete list of all bugfixes and feature changes in MySQL Cluster, please refer to the changelog section for each individual MySQL Cluster release.

An overview of features added in MySQL 5.1 not specific to MySQL Cluster can be found here: [Section 1.5.1, “What’s New in MySQL 5.1”](#). For a complete list of all bugfixes and features changes made in MySQL 5.1 that are not specific to MySQL Cluster, see [Section C.1, “Changes in release 5.1.x \(Development\)”](#).

### 19.17.1. Changes in MySQL Cluster NDB 6.3

This section contains change history information for MySQL Cluster releases based on version 6.3 of the `NDBCLUSTER` storage engine.

For an overview of new features added in MySQL Cluster NDB 6.3, see [Section 19.15.4, “Features Added in MySQL Cluster NDB 6.3”](#).

### 19.17.1.1. Changes in MySQL Cluster NDB 6.3.16 (5.1.24-ndb-6.3.16) (27 June 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9, “MySQL Installation Using a Source Distribution”](#), and in [Section 19.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see [Section C.1.4, “Changes in MySQL 5.1.24 \(08 April 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** Event buffer lag reports are now written to the cluster log. ([Bug#37427](#))
- **MySQL Cluster:** Added the `--no-binlog` option for `ndb_restore`. When used, this option prevents information being written to SQL node binary logs from the restoration of a cluster backup. ([Bug#30452](#))

Bugs fixed:

- **Cluster API: MySQL Cluster:** Changing the system time on data nodes could cause MGM API applications to hang and the data nodes to crash. ([Bug#35607](#))
- **MySQL Cluster:** Failure of a data node could sometimes cause mysqld to crash. ([Bug#37628](#))
- **MySQL Cluster:** `DELETE ... WHERE unique_index_column=value` deleted the wrong row from the table. ([Bug#37516](#))
- **MySQL Cluster:** If subscription was terminated while a node was down, the epoch was not properly acknowledged by that node. ([Bug#37442](#))
- **MySQL Cluster:** `libmysqld` failed to wait for the cluster binlog thread to terminate before exiting. ([Bug#37429](#))
- **MySQL Cluster:** In rare circumstances, a connection followed by a disconnection could give rise to a “stale” connection where the connection still existed but was not seen by the transporter. ([Bug#37338](#))
- **MySQL Cluster:** Queries against `NDBCLUSTER` tables were cached only if `AUTOCOMMIT` was in use. ([Bug#36692](#))
- **Cluster Replication:** Data was written to the binlog with `--log-slave-updates` disabled. ([Bug#37472](#))
- **Cluster API:** Creating a table on an SQL node, then starting an NDB API application that listened for events from this table, then dropping the table from an SQL node, prevented data node restarts. ([Bug#37279](#))
- **Cluster API:** When some operations succeeded and some failed following a call to `NdbTransaction::execute(Commit, AO_IgnoreOnError)`, a race condition could cause spurious occurrences of NDB API Error 4011 (`INTERNAL ERROR`). ([Bug#37158](#))

### 19.17.1.2. Changes in MySQL Cluster NDB 6.3.15 (5.1.24-ndb-6.3.15) (30 May 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9, “MySQL Installation Using a Source Distribution”](#), and in [Section 19.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes

and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see [Section C.1.4, “Changes in MySQL 5.1.24 \(08 April 2008\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** In certain rare situations, `ndb_size.pl` could fail with the error `CAN'T USE STRING ("VALUE") AS A HASH REF WHILE "STRICT REFS" IN USE.` ([Bug#43022](#))
- **MySQL Cluster:** Under some circumstances, a failed `CREATE TABLE` could mean that subsequent `CREATE TABLE` statements caused node failures. ([Bug#37092](#))
- **MySQL Cluster:** A fail attempt to create an `NDB` table could in some cases lead to resource leaks or cluster failures. ([Bug#37072](#))
- **MySQL Cluster:** Attempting to create a native backup of `NDB` tables having a large number of `NULL` columns and data could lead to node failures. ([Bug#37039](#))
- **MySQL Cluster:** Checking of API node connections was not efficiently handled. ([Bug#36843](#))
- **MySQL Cluster:** Attempting to delete a non-existent row from a table containing a `TEXT` or `BLOB` column within a transaction caused the transaction to fail. ([Bug#36756](#))

See also [Bug#36851](#)

- **MySQL Cluster:** If the combined total of tables and indexes in the cluster was greater than 4096, issuing `START BACKUP` caused data nodes to fail. ([Bug#36044](#))
- **MySQL Cluster:** Where column values to be compared in a query were of the `VARCHAR` or `VARBINARY` types, `NDB-CLUSTER` passed a value padded to the full size of the column, which caused unnecessary data to be sent to the data nodes. This also had the effect of wasting CPU and network bandwidth, and causing condition pushdown to be disabled where it could (and should) otherwise have been applied. ([Bug#35393](#))
- **MySQL Cluster:** When dropping a table failed for any reason (such as when in single user mode) then the corresponding `.ndb` file was still removed.
- **Replication:** When flushing tables, there were a slight chance that the flush occurred between the processing of one table map event and the next. Since the tables were opened one by one, subsequent locking of tables would cause the slave to crash. This problem was observed when replicating `NDBCLUSTER` or `InnoDB` tables, when executing multi-table updates, and when a trigger or a stored routine performed an (additional) insert on a table so that two tables were effectively being inserted into in the same statement. ([Bug#36197](#))
- **Cluster API:** Ordered index scans were not pruned correctly where a partitioning key was specified with an EQ-bound. ([Bug#36950](#))
- **Cluster API:** When an insert operation involving `BLOB` data was attempted on a row which already existed, no duplicate key error was correctly reported and the transaction is incorrectly aborted. In some cases, the existing row could also become corrupted. ([Bug#36851](#))

See also [Bug#26756](#)

### 19.17.1.3. Changes in MySQL Cluster NDB 6.3.14 (5.1.24-ndb-6.3.14) (11 May 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9, “MySQL Installation Using a Source Distribution”](#), and in [Section 19.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see [Section C.1.4, “Changes in MySQL 5.1.24 \(08 April 2008\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** `SET GLOBAL ndb_extra_logging` caused `mysqld` to crash. (Bug#36547)
- **MySQL Cluster:** A race condition caused by a failure in `epoll` handling could cause data nodes to fail. (Bug#36537)
- **MySQL Cluster:** Under certain rare circumstances, the failure of the new master node while attempting a node takeover would cause takeover errors to repeat without being resolved. (Bug#36199, Bug#36246, Bug#36247, Bug#36276)
- **MySQL Cluster:** When more than one SQL node connected to the cluster at the same time, creation of the `mysql.ndb_schema` table failed on one of them with an explicit `TABLE EXISTS` error, which was not necessary. (Bug#35943)
- **MySQL Cluster:** `mysqld` failed to start after running `mysql_upgrade`. (Bug#35708)
- **MySQL Cluster:** Notification of a cascading master node failures could sometimes not be transmitted correctly (that is, transmission of the `NF_COMPLETTEREP` signal could fail), leading to transactions hanging and timing out (NDB error 4012), scans hanging, and failure of the management server process. (Bug#32645)
- **MySQL Cluster:** If an API node disconnected and then reconnected during Start Phase 8, then the connection could be “blocked” — that is, the `QMGR` kernel block failed to detect that the API node was in fact connected to the cluster, causing issues with the NDB Subscription Manager (SUMA).
- **MySQL Cluster:** NDB error 1427 (`API NODE DIED, WHEN SUB_START_REQ REACHED NODE`) was incorrectly classified as a schema error rather than a temporary error.
- **Cluster Replication:** Performing `SELECT ... FROM mysql.ndb_apply_status` before the `mysqld` process had connected to the cluster failed, and caused this table never to be created. (Bug#36123)
- **Cluster API:** Accessing the debug version of `libndbclient` via `dlopen()` resulted in a segmentation fault. (Bug#35927)
- **Cluster API:** Attempting to pass a nonexistent column name to the `equal()` and `setValue()` methods of `NdbOperation` caused NDB API applications to crash. Now the column name is checked, and an error is returned in the event that the column is not found. (Bug#33747)
- **Cluster API:** Relocation errors were encountered when trying to compile NDB API applications on a number of platforms, including 64-bit Linux. As a result, `libmysys`, `libmystrings`, and `libdbug` have been changed from normal libraries to “noinst” `libtool` helper libraries. They are no longer installed as separate libraries; instead, all necessary symbols from these are added directly to `libndbclient`. This means that NDB API programs now need to be linked only using `-lndbclient`. (Bug#29791)

#### 19.17.1.4. Changes in MySQL Cluster NDB 6.3.13 (5.1.24-ndb-6.3.13) (10 April 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9, “MySQL Installation Using a Source Distribution”](#), and in [Section 19.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see [Section C.1.4, “Changes in MySQL 5.1.24 \(08 April 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Important Change: MySQL Cluster:** `mysqld_safe` now traps Signal 13 (`SIGPIPE`) so that this signal no longer kills the MySQL server process. (Bug#33984)
- **MySQL Cluster:** Node or system restarts could fail due an uninitialized variable in the `DTUP` kernel block. This issue was found

in MySQL Cluster NDB 6.3.11. ([Bug#35797](#))

- **MySQL Cluster:** If an error occurred while executing a statement involving a `BLOB` or `TEXT` column of an `NDB` table, a memory leak could result. ([Bug#35593](#))
- **MySQL Cluster:** It was not possible to determine the value used for the `--ndb-cluster-connection-pool` option in the `mysql` client. Now this value is reported as a system status variable. ([Bug#35573](#))
- **MySQL Cluster:** The `ndb_waiter` utility wrongly calculated timeouts. ([Bug#35435](#))
- **MySQL Cluster:** A `SELECT` on a table with a non-indexed, large `VARCHAR` column which resulted in condition pushdown on this column could cause `mysqld` to crash. ([Bug#35413](#))
- **MySQL Cluster:** `ndb_restore` incorrectly handled some datatypes when applying log files from backups. ([Bug#35343](#))
- **MySQL Cluster:** In some circumstances, a stopped data node was handled incorrectly, leading to redo log space being exhausted following an initial restart of the node, or an initial or partial restart of the cluster (the wrong CGI might be used in such cases). This could happen, for example, when a node was stopped following the creation of a new table, but before a new LCP could be executed. ([Bug#35241](#))
- **MySQL Cluster:** `SELECT ... LIKE ...` queries yielded incorrect results when used on `NDB` tables. As part of this fix, condition pushdown of such queries has been disabled; re-enabling it is expected to be done as part of a later, permanent fix for this issue. ([Bug#35185](#))
- **MySQL Cluster:** `ndb_mgmd` reported errors to `STDOUT` rather than to `STDERR`. ([Bug#35169](#))
- **MySQL Cluster:** Nested multi-range reads failed when the second multi-range read released the first read's unprocessed operations, sometimes leading to a SQL node crash. ([Bug#35137](#))
- **MySQL Cluster:** In some situations, a problem with synchronizing checkpoints between nodes could cause a system restart or a node restart to fail with `ERROR 630 DURING RESTORE OF TX`. ([Bug#34756](#))
- **MySQL Cluster:** A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. ([Bug#34702](#))
- **MySQL Cluster:** When a secondary index on a `DECIMAL` column was used to retrieve data from an `NDB` table, no results were returned even if the target table had a matched value in the column that was defined with the secondary index. ([Bug#34515](#))
- **MySQL Cluster:** An `UPDATE` on an `NDB` table that set a new value for a unique key column could cause subsequent queries to fail. ([Bug#34208](#))
- **MySQL Cluster:** If a data node in one node group was placed in the “not started” state (using `node_id RESTART -n`), it was not possible to stop a data node in a different node group. ([Bug#34201](#))
- **MySQL Cluster:** If a `START BACKUP` command was issued while `ndb_restore` was running, the backup being restored could be overwritten. ([Bug#26498](#))
- **MySQL Cluster:** `REPLACE` statements did not work correctly with `NDBCLUSTER` tables when all columns were not explicitly listed. ([Bug#22045](#))
- **Replication:** A `CHANGE MASTER` statement with no `MASTER_HEARTBEAT_PERIOD` option failed to reset the heartbeat period to its default value. ([Bug#34686](#))
- **Cluster Replication:** In some cases, when updating only one or some columns in a table, the complete row was written to the binary log instead of only the updated column or columns, even when `ndb_log_updated_only` was set to 1. ([Bug#35208](#))
- **Cluster Replication:** The `--ndb-wait-connected` option caused the server to wait for a partial connection plus an additional 3 seconds for a complete connection to the cluster. This could lead to issues with setting up the binary log. ([Bug#34757](#))
- **Cluster API:** Some ordered index scans could return tuples out of order. ([Bug#35908](#))
- **Cluster API:** `NdbScanFilter::getNdbOperation()`, which was inadvertently removed in MySQL Cluster NDB 6.3.11, has been restored. ([Bug#35854](#))
- **Cluster API:** `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. ([Bug#35853](#))
- **Cluster API:** `mgmapi.h` contained constructs which only worked in C++, but not in C. ([Bug#27004](#))
- Enabling the `read_only` system variable while autocommit mode was enabled caused `SELECT` statements for transactional

storage engines to fail. ([Bug#35732](#))

- Executing a `FLUSH PRIVILEGES` statement after creating a temporary table in the `mysql` database with the same name as one of the MySQL system tables caused the server to crash.

#### Note

While it is possible to shadow a system table in this way, the temporary table exists only for the current user and connection, and does not effect any user privileges. ([Bug#33275](#))

### 19.17.1.5. Changes in MySQL Cluster NDB 6.3.12 (5.1.23-ndb-6.3.12) (05 April 2008)

MySQL Cluster NDB 6.3.12 was pulled due to issues discovered shortly after its release, and is no longer available. Users of MySQL Cluster NDB 6.3.10 and earlier MySQL Cluster NDB 6.3 releases should upgrade to MySQL Cluster NDB 6.3.13 or later.

For information about bugfixes and feature enhancements that were originally scheduled to appear for the first time in this release, see [Section 19.17.1.4, “Changes in MySQL Cluster NDB 6.3.13 \(5.1.24-ndb-6.3.13\) \(10 April 2008\)”](#).

### 19.17.1.6. Changes in MySQL Cluster NDB 6.3.11 (5.1.23-ndb-6.3.11) (28 March 2008)

This release was pulled due to issues discovered shortly after its release, and is no longer available. Users of MySQL Cluster NDB 6.3.10 and earlier MySQL Cluster NDB 6.3 releases should upgrade to MySQL Cluster NDB 6.3.13 or later.

For information about bugfixes and feature enhancements that were originally scheduled to appear for the first time in this release, see [Section 19.17.1.4, “Changes in MySQL Cluster NDB 6.3.13 \(5.1.24-ndb-6.3.13\) \(10 April 2008\)”](#).

### 19.17.1.7. Changes in MySQL Cluster NDB 6.3.10 (5.1.23-ndb-6.3.10) (17 February 2008)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9, “MySQL Installation Using a Source Distribution”](#), and in [Section 19.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.5, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** Due to the reduction of the number of local checkpoints from 3 to 2 in MySQL Cluster NDB 6.3.8, a data node using `ndbd` from MySQL Cluster NDB 6.3.8 or later started using a filesystem from an earlier version could incorrectly invalidate local checkpoints too early during the startup process, causing the node to fail. ([Bug#34596](#))

### 19.17.1.8. Changes in MySQL Cluster NDB 6.3.9 (5.1.23-ndb-6.3.9) (12 February 2008)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9, “MySQL Installation Using a Source Distribution”](#), and in [Section 19.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.5, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Beginning with this version, MySQL Cluster NDB 6.3.x releases once again include the `InnoDB` storage engine. In order to enable `InnoDB`, you must configure the build using `--with-innodb`.

Bugs fixed:

- MySQL Cluster:** Cluster failures could sometimes occur when performing more than three parallel takeovers during node restarts or system restarts. This affected MySQL Cluster NDB 6.3.x releases only. ([Bug#34445](#))
- MySQL Cluster:** Upgrades of a cluster using while a `DataMemory` setting in excess of 16 GB caused data nodes to fail. ([Bug#34378](#))
- MySQL Cluster:** Performing many SQL statements on `NDB` tables while in `AUTOCOMMIT` mode caused a memory leak in `mysqld`. ([Bug#34275](#))
- MySQL Cluster:** Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. ([Bug#34216](#))
- MySQL Cluster:** When configured with `NDB` support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. ([Bug#34169](#))
- MySQL Cluster:** The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. ([Bug#34160](#))
- MySQL Cluster:** Extremely long `SELECT` statements (where the text of the statement was in excess of 50000 characters) against `NDB` tables returned empty results. ([Bug#34107](#))
- MySQL Cluster:** When configured with `NDB` support, MySQL failed to compile on 64bit FreeBSD systems. ([Bug#34046](#))

See also [Bug#32175](#)

- MySQL Cluster:** Statements executing multiple inserts performed poorly on `NDB` tables having `AUTO_INCREMENT` columns. ([Bug#33534](#))
- MySQL Cluster:** The `ndb_waiter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. ([Bug#32025](#))

See also [Bug#32023](#)

- MySQL Cluster:** Transaction atomicity was sometimes not preserved between reads and inserts under high loads. ([Bug#31477](#))
- MySQL Cluster:** Having tables with a great many columns could cause Cluster backups to fail. ([Bug#30172](#))
- Cluster Replication: Disk Data:** Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. ([Bug#34118](#))
- Disk Data:** Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. ([Bug#33619](#))
- Cluster Replication:** Setting `--replicate-ignore-db=mysql` caused the `mysql.ndb_apply_status` table not to be replicated, breaking Cluster Replication. ([Bug#28170](#))

### 19.17.1.9. Changes in MySQL Cluster NDB 6.3.8 (5.1.23-ndb-6.3.8) (29 January 2008)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9, “MySQL Installation Using a Source Distribution”](#), and in [Section 19.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.5, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster API: Important Change:** Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See [The `Ndb\_logevent\_type` Type](#), for more information about `NDB_LE_MemoryUsage`. (Bug#30271)
- **MySQL Cluster:** `ndb_restore` now supports basic *attribute promotion*; that is, data from a column of a given type can be restored to a column using a “larger” type. For example, Cluster backup data taken from a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column.

For more information, see [Section 19.9.3, “`ndb\_restore` — Restore a Cluster Backup”](#).

- **MySQL Cluster:** Now only 2 local checkpoints are stored, rather than 3 as in previous MySQL Cluster versions. This lowers disk space requirements and reduces the size and number of redo log files needed.
- **MySQL Cluster:** The `mysqld` option `--ndb-batch-size` has been added. This allows for controlling the size of batches used for running transactions.
- **MySQL Cluster:** Node recovery can now be done in parallel, rather than sequentially, which can result in much faster recovery times.
- **MySQL Cluster:** Persistence of `NDB` tables can now be controlled using the session variables `ndb_table_temporary` and `ndb_table_no_logging`. `ndb_table_no_logging` causes `NDB` tables not to be checkpointed to disk; `ndb_table_temporary` does the same, and in addition, no schema files are created.
- **MySQL Cluster:** `OPTIMIZE TABLE` can now be interrupted. This can be done, for example, by killing the SQL thread performing the `OPTIMIZE` operation.

Bugs fixed:

- **Disk Data: Important Change:** It is no longer possible on 32-bit systems to issue statements appearing to create Disk Data log files or data files greater than 4 GB in size. (Trying to create log files or data files larger than 4 GB on 32-bit systems led to unrecoverable data node failures; such statements now fail with `NDB` error 1515.) (Bug#29186)
- **Replication: MySQL Cluster:** The code implementing heartbeats did not check for possible errors in some circumstances; this kept the dump thread hanging while waiting for heartbeats loop even though the slave was no longer connected. (Bug#33332)
- **MySQL Cluster:** High numbers of insert operations, delete operations, or both could cause `NDB` error 899 (`ROWID ALREADY ALLOCATED`) to occur unnecessarily. (Bug#34033)
- **MySQL Cluster:** A periodic failure to flush the send buffer by the `NDB` TCP transporter could cause an unnecessary delay of 10 ms between operations. (Bug#34005)
- **MySQL Cluster:** `DROP TABLE` did not free all data memory. This bug was observed in MySQL Cluster NDB 6.3.7 only. (Bug#33802)
- **MySQL Cluster:** A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. (Bug#33793)
- **MySQL Cluster:** Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. (Bug#33739)
- **MySQL Cluster:** A failure to initialize an internal variable led to sporadic crashes during cluster testing. (Bug#33715)
- **MySQL Cluster:** The server failed to reject properly the creation of an `NDB` table having an unindexed `AUTO_INCREMENT` column. (Bug#30417)
- **MySQL Cluster:** Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE`

statement on an NDB table failed with NDB error 4350 `TRANSACTION ALREADY ABORTED`. (Bug#29851)

- **MySQL Cluster:** The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. (Bug#28647)
- **MySQL Cluster:** It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum allowed value. (Bug#28298)
- **MySQL Cluster:** Under some circumstances, a recovering data node did not use its own data, instead copying data from another node even when this was not required. This in effect bypassed the optimized node recovery protocol and caused recovery times to be unnecessarily long. (Bug#26913)
- **Cluster Replication:** Consecutive DDL statements involving tables (`CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE`) could be executed so quickly that previous DDL statements upon which they depended were not yet written in the binary log.

For example, if `DROP TABLE foo` was issued immediately following `CREATE TABLE foo`, the `DROP` statement could fail because the `CREATE` had not yet been recorded. (Bug#34006)

- **Cluster Replication:** `ndb_restore -e` restored excessively large values to the `ndb_apply_status` table's `epoch` column when restoring to a MySQL Cluster version supporting Micro-GCPs from an older version that did not support these. A workaround when restoring to MySQL Cluster releases supporting micro-GCPs previous to MySQL Cluster NDB 6.3.8 is to perform a 32-bit shift on the `epoch` column values to reduce them to their proper size. (Bug#33406)
- **Cluster API:** Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` equal to 0. (Bug#33895)
- **Cluster API:** When reading a `BIT(64)` value using `NdbOperation::getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. (Bug#33750)

### 19.17.1.10. Changes in MySQL Cluster NDB 6.3.7 (5.1.23-ndb-6.3.7) (19 December 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in Section 2.9, “MySQL Installation Using a Source Distribution”, and in Section 19.3.1, “Building MySQL Cluster from Source Code”. You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see Section C.1.5, “Changes in MySQL 5.1.23 (29 January 2008)”).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** Compressed local checkpoints and backups are now supported, resulting in a space savings of 50% or more over uncompressed LCPs and backups. Compression of these can be enabled in the `config.ini` file using the two new data node configuration parameters `CompressedLCP` and `CompressedBackup`, respectively.
- **MySQL Cluster:** `OPTIMIZE TABLE` is now supported for NDB tables, subject to the following limitations:
  - Only in-memory tables are supported. `OPTIMIZE` still has no effect on Disk Data tables.
  - Only variable-length columns are supported. However, you can force columns defined using fixed-length data types to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement. Memory reclaimed from an NDB table using `OPTIMIZE` is generally available to the cluster, and not confined to the table from which it was recovered, unlike the case with memory freed using `DELETE`.

The performance of `OPTIMIZE` on NDB tables can be regulated by adjusting the value of the `ndb_optimization_delay` system variable.

- **MySQL Cluster:** It is now possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` to 1 or ON.

### Note

To use this feature, autocommit must be disabled.

Bugs fixed:

- **Important Change: MySQL Cluster:** `AUTO_INCREMENT` columns had the following problems when used in NDB tables:
  - The `AUTO_INCREMENT` counter was not updated correctly when such a column was updated.
  - `AUTO_INCREMENT` values were not prefetched beyond statement boundaries.
  - `AUTO_INCREMENT` values were not handled correctly with `INSERT IGNORE` statements.
  - After being set, `ndb_autoincrement_prefetch_sz` showed a value of 1, regardless of the value it had actually been set to.  
As part of this fix, the behavior of `ndb_autoincrement_prefetch_sz` has changed. Setting this to less than 32 no longer has any effect on prefetching within statements (where IDs are now always obtained in batches of 32 or more), but only between statements. The default value for this variable has also changed, and is now 1. (Bug#25176, Bug#31956, Bug#32055)
- **Partitioning: MySQL Cluster:** When partition pruning on an NDB table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC, MAX()` to be handled incorrectly, and similar problems. (Bug#33061)
- **MySQL Cluster:** When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. (Bug#33237)
- **MySQL Cluster:** When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. (Bug#32922)
- **MySQL Cluster:** Under some conditions, performing an `ALTER TABLE` on an NDBCLUSTER table failed with a `TABLE IS FULL` error, even when only 25% of `DataMemory` was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). (Bug#32670)
- **Cluster Replication:** Creating the `mysql.ndb_replication` table with the wrong number of columns for the primary key caused `mysqld` to crash. Now a `CREATE TABLE [mysql.]ndb_replication` statement that is invalid for this reason fails with the error `BAD SCHEMA FOR MYSQL.NDB_REPLICATION TABLE. MESSAGE: WRONG NUMBER OF PRIMARY KEYS, EXPECTED NUMBER.` (Bug#33159)
- **Cluster Replication:** Where a table being replicated had a `TEXT` or `BLOB` column, an `UPDATE` on the master that did not refer explicitly to this column in the `WHERE` clause stopped the SQL thread on the slave with `ERROR IN WRITE_ROWS EVENT: ROW APPLICATION FAILED. GOT ERROR 4288 'BLOB HANDLE FOR COLUMN NOT AVAILABLE' FROM NDBCLUSTER.` (Bug#30674)

## 19.17.1.11. Changes in MySQL Cluster NDB 6.3.6 (5.1.22-ndb-6.3.6) (08 November 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in Section 2.9, “MySQL Installation Using a Source Distribution”, and in Section 19.3.1, “Building MySQL Cluster from Source Code”. You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Section C.1.6, “Changes in MySQL 5.1.22 (24 September 2007: Release Candidate)”).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Note:** MySQL Cluster NDB 6.2 and 6.3 source archives are now available in separate commercial and GPL versions. Due to licensing concerns, previous MySQL Cluster NDB 6.2 and 6.3 source archives were removed from the FTP site.
- **MySQL Cluster:** Unnecessary reads when performing a primary key or unique key update have been reduced, and in some cases, eliminated. (It is almost never necessary to read a record prior to an update, the lone exception to this being when a primary key is updated, since this requires a delete followed by an insert, which must be prepared by reading the record.) Depending on the number of primary key and unique key lookups that are performed per transaction, this can yield a considerable improvement in performance.
- **MySQL Cluster:** Batched operations are now better supported for `DELETE` and `UPDATE`. (`UPDATE WHERE . . .` and multiple `DELETE`.)
- **MySQL Cluster:** Introduced the `Ndb_execute_count` status variable, which measures the number of round trips made by queries to the NDB kernel.

Bugs fixed:

- **MySQL Cluster:** An insert or update with combined range and equality constraints failed when run against an NDB table with the error `GOT UNKNOWN ERROR FROM NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. (Bug#31874)
- **MySQL Cluster:** An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in NDB tables. (Bug#31810)
- **MySQL Cluster:** The NDB storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. (Bug#31761)
- **MySQL Cluster:** `ndb_restore` displayed incorrect backup file version information. This meant (for example) that, when attempting to restore a backup made from a MySQL 5.1.22 cluster to a MySQL Cluster NDB 6.3.3 cluster, the restore process failed with the error `RESTORE PROGRAM OLDER THAN BACKUP VERSION. NOT SUPPORTED. USE NEW RESTORE PROGRAM`. (Bug#31723)
- **MySQL Cluster:** Following an upgrade, `ndb_mgmd` would fail with an `ArbitrationError`. (Bug#31690)
- **MySQL Cluster:** The NDB management client command `node_id REPORT MEMORY` provided no output when `node_id` was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node node_id: is not a data node`. (Bug#29485)
- **MySQL Cluster:** Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. (Bug#26450)
- **MySQL Cluster:** `UPDATE IGNORE` could sometimes fail on NDB tables due to the use of uninitialized data when checking for duplicate keys to be ignored. (Bug#25817)
- **Cluster Replication:** Updates performed unnecessary writes to the primary keys of the rows being updated. (Bug#31841)
- **Cluster Replication:** Slave batching did not work correctly with `UPDATE` statements. (Bug#31787)
- **Cluster Replication:** A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. (Bug#31701)
- **Cluster Replication:** When the master `mysqld` crashed or was restarted, no `LOST_EVENTS` entry was made in the binlog. (Bug#31484)

See also [Bug#21494](#)

### 19.17.1.12. Changes in MySQL Cluster NDB 6.3.5 (5.1.22-ndb-6.3.5) (17 October 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9, “MySQL Installation Using a Source Distribution”](#), and in [Section 19.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.6, “Changes in MySQL 5.1.22 \(24 September 2007: Release Candidate\)”](#)).

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** A query against a table with `TEXT` or `BLOB` columns that would return more than a certain amount of data failed with `GOT ERROR 4350 'TRANSACTION ALREADY ABORTED' FROM NDBCLUSTER`. (Bug#31482)

This regression was introduced by Bug#29102

- **Cluster Replication:** In some cases, not all tables were properly initialized before the binlog thread was started. (Bug#31618)

### 19.17.1.13. Changes in MySQL Cluster NDB 6.3.4 (5.1.22-ndb-6.3.4) (15 October 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9, “MySQL Installation Using a Source Distribution”](#), and in [Section 19.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.6, “Changes in MySQL 5.1.22 \(24 September 2007: Release Candidate\)”](#)).

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** The `--ndb_optimized_node_selection` startup option for `mysqld` now allows a wider range of values and corresponding behaviors for SQL nodes when selecting a transaction coordinator. See [Section 5.1.3, “System Variables”](#), for more information.
- **Cluster Replication:** A new configuration parameter `TimeBetweenEpochsTimeout` allows a timeout to be set for time between epochs. For more information, see [Section 19.3.4.5, “Defining Data Nodes”](#). (Bug#31276)
- **Cluster Replication:** A replication heartbeat mechanism has been added to facilitate monitoring. This provides an alternative to checking log files, making it possible to detect in real time when a slave has failed.

Configuration of heartbeats is done via a new `MASTER_HEARTBEAT_PERIOD = interval` clause for the `CHANGE MASTER TO` statement (see [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#)); monitoring can be done by checking the values of the status variables `Slave_heartbeat_period` and `Slave_received_heartbeats` (see [Section 5.1.6, “Status Variables”](#)).

The addition of replication heartbeats addresses a number of issues:

- Relay logs were rotated every `slave_net_timeout` seconds even if no statements were being replicated.
- `SHOW SLAVE STATUS` displayed an incorrect value for `seconds_behind_master` following a `FLUSH LOGS` statement.
- Replication master-slave connections used `slave_net_timeout` for connection timeouts. (Bug#20435, Bug#29309, Bug#30932)
- **Cluster Replication:** Support for a new conflict resolution function `NDB$OLD()` has been added for handling simultaneous updates in multi-master and circular replication setups. A new status variable `Ndb_conflict_fn_old` tracks the number of times that updates are prevented from being applied due to this type of conflict resolution. See [Section 19.11.10, “MySQL Cluster Replication Conflict Resolution”](#), for more information.
- On MySQL replication slaves having multiple network interfaces, it is now possible to set which interface to use for connecting to the master. This can be done by using either the `mysqld` startup option `--master-bind` or the `MASTER_BIND='interface'` clause in a `CHANGE MASTER` statement. (Bug#25939)

- Additional checks were implemented to catch unsupported online `ALTER TABLE` operations. Currently it is not possible to reorder columns or to change the storage engine used for a table via online `ALTER`.

Some redundant checks made during online creation of indexes were removed.

- A `--bind-address` option has been added to a number of MySQL client programs: `mysql`, `mysqldump`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqlimport`, and `mysqlshow`. This is for use on a computer having multiple network interfaces, and allows you to choose which interface is used to connect to the MySQL server.

Bugs fixed:

- **MySQL Cluster:** It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. (Bug#31525)
- **MySQL Cluster:** NDB tables having names containing non-alphanumeric characters (such as “ \$ ”) were not discovered correctly. (Bug#31470)
- **MySQL Cluster:** A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. (Bug#31257)
- **MySQL Cluster:** Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. (Bug#30379)
- **MySQL Cluster:** In some cases, the cluster management server logged entries multiple times following a restart of `mgmd`. (Bug#29565)
- **MySQL Cluster:** `ndb_mgm --help` did not display any information about the `-a` option. (Bug#29509)
- **MySQL Cluster:** An interpreted program of sufficient size and complexity could cause all cluster data nodes to shut down due to buffer overruns. (Bug#29390)
- **MySQL Cluster:** The cluster log was formatted inconsistently and contained extraneous newline characters. (Bug#25064)
- A transaction was not aborted following the failure of statement. (Bug#31320)
- Online `ALTER` operations involving a column whose data type has an implicit default value left behind temporary `.FRM` files, causing subsequent `DROP DATABASE` statements to fail. (Bug#31097)
- Errors could sometimes occur during an online `ADD COLUMN` under load. (Bug#31082)
- Transactions were committed prematurely when `LOCK TABLE` and `SET AUTOCOMMIT=OFF` were used together. (Bug#30996)
- A cluster restart could sometimes fail due to an issue with table IDs. (Bug#30975)
- The `mysqld_safe` script contained a syntax error. (Bug#30624)

#### 19.17.1.14. Changes in MySQL Cluster NDB 6.3.3 (5.1.22-ndb-6.3.3) (20 September 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9](#), “MySQL Installation Using a Source Distribution”, and in [Section 19.3.1](#), “Building MySQL Cluster from Source Code”. You can download the GPL source tarball from the MySQL FTP site at [http://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](http://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.6](#), “Changes in MySQL 5.1.22 (24 September 2007: Release Candidate)”).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. (Bug#28423)
- **Cluster Replication:** A server status variable `ndb_conflict_fn_max` now provides a count of the number of times that conflict resolution for MySQL Cluster Replication has been applied.

See Section 19.11.10, “MySQL Cluster Replication Conflict Resolution”, for more information.

Bugs fixed:

- **Partitioning: MySQL Cluster:** `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL hash function than the hash function used in the `NDB` storage engine. (Bug#29550)
- **MySQL Cluster:** Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. (Bug#29674)
- **MySQL Cluster:** The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. (Bug#27683)
- **MySQL Cluster:** Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATETIME` columns. (Bug#27543, Bug#30024)
- Errors could sometimes occur during an online `ADD COLUMN` under load. (Bug#31082)

### 19.17.1.15. Changes in MySQL Cluster NDB 6.3.2 (5.1.22-ndb-6.3.2) (07 September 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in Section 2.9, “MySQL Installation Using a Source Distribution”, and in Section 19.3.1, “Building MySQL Cluster from Source Code”. You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see Section C.1.6, “Changes in MySQL 5.1.22 (24 September 2007: Release Candidate)”).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed online for `NDB` tables, as well as online renaming of tables and columns for `NDB` and `MyISAM` tables — that is, without copying or locking of the affected tables — using `ALTER ONLINE TABLE`.

Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

See Section 12.1.4, “ALTER TABLE Syntax”, Section 12.1.7, “CREATE INDEX Syntax”, and Section 12.1.13, “DROP INDEX Syntax”, for more information.

- **MySQL Cluster:** It is now possible to control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

It is also possible to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see Section 12.1.10, “CREATE TABLE Syntax”.

- **MySQL Cluster:** A new cluster management server startup option `--bind-address` makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see Section 19.6.5.2, “Command Op-

tions for `ndb_mgmd`”.

- **Cluster Replication: Replication:** The protocol for handling global checkpoints has been changed. It is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` configuration parameter. This improves the reliability and performance of MySQL Cluster Replication.

GCPs handled using the new protocol are sometimes referred to as “micro-GCPs”.

For more information, see `TimeBetweenEpochs` .

- **Cluster Replication:** Multi-way replication failover and recovery for NDB is facilitated with the introduction of the `-ndb-log-orig` option. When `mysqld` is started with this option, the originating server ID and epoch of each binlog event is recorded in the `mysql.ndb_binlog_index` table, which now contains two additional columns `orig_server_id` and `orig_epoch` for storing this information. In such cases, a single epoch on a slave may be represented by multiple rows in the slave's `ndb_binlog_index` table, one for each epoch as it originated from a master.

Bugs fixed:

- **MySQL Cluster:** An insufficiently descriptive and potentially misleading Error 4006 (`CONNECT FAILURE - OUT OF CONNECTION OBJECTS...`) was produced when either of the following two conditions occurred:
  1. There were no more transaction records in the transaction coordinator
  2. an `Ndb` object in the NDB API was initialized with insufficient parallelism  
Separate error messages are now generated for each of these two cases. ([Bug#11313](#))
- **Cluster API:** An `Ndb` object in the NDB API was initialized with insufficient parallelism.
- For micro-GCPs, fixed the assignment of “fake” CGI events so that they do not cause buckets to be sent out of order. Now, when assigning a GCI to a non-GCI event (that is, creating a pseudo-GCI or “fake” CGI), the GCI that is to arrive is always initiated, even if no known GCI exists, which could occur in the event of a node failure. ([Bug#30884](#))
- When an NDB event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. ([Bug#30877](#))
- There were no more transaction records in the transaction coordinator

### 19.17.1.16. Changes in MySQL Cluster NDB 6.3.1 (5.1.19-ndb-6.3.1) (04 July 2007)

This is a new Beta development release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9, “MySQL Installation Using a Source Distribution”](#), and in [Section 19.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see [Section C.1.9, “Changes in MySQL 5.1.19 \(25 May 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Batching of transactions was not handled correctly in some cases. ([Bug#29525](#))

### 19.17.1.17. Changes in MySQL Cluster NDB 6.3.0 (5.1.19-ndb-6.3.0) (02 July 2007)

This is the first development release for MySQL Cluster NDB 6.3, based on version 6.3 of the `NDBCLUSTER` storage engine.

**Obtaining MySQL Cluster NDB 6.3.** MySQL Cluster NDB 6.3 releases are source-only releases which you must compile and install using the instructions found in [Section 2.9, “MySQL Installation Using a Source Distribution”](#), and in [Section 19.3.1, “Building MySQL Cluster from Source Code”](#). You can download the GPL source tarball from the MySQL FTP site at

[ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and feature changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see [Section C.1.9, “Changes in MySQL 5.1.19 \(25 May 2007\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** Reporting functionality has been significantly enhanced in this release:
  - A new configuration parameter `BackupReportFrequency` now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels). See [Section 19.3.4.5, “Defining Data Nodes”](#), for more information about this parameter.
  - A new `REPORT` command has been added in the cluster management client. `REPORT BackupStatus` allows you to obtain a backup status report at any time during a backup. `REPORT MemoryUsage` reports the current data memory and index memory used by each data node. For more about the `REPORT` command, see [Section 19.7.2, “Commands in the MySQL Cluster Management Client”](#).
  - `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.
- **MySQL Cluster:** A new configuration parameter `ODirect` causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.
- **Cluster Replication:** This release implements conflict resolution, which makes it possible to determine on a per-table basis whether or not an update to a given row on the master should be applied on the slave. For more information, see [Section 19.11.10, “MySQL Cluster Replication Conflict Resolution”](#).

## 19.17.2. Changes in MySQL Cluster NDB 6.2

This section contains change history information for MySQL Cluster releases based on version 6.2 of the `NDBCLUSTER` storage engine.

For an overview of new features added in MySQL Cluster NDB 6.2, see [Section 19.15.3, “Features Added in MySQL Cluster NDB 6.2”](#).

### 19.17.2.1. Changes in MySQL Cluster NDB 6.2.16 (5.1.24-ndb-6.2.16) (Not yet released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see [Section C.1.4, “Changes in MySQL 5.1.24 \(08 April 2008\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** Event buffer lag reports are now written to the cluster log. ([Bug#37427](#))
- **MySQL Cluster:** Added the `--no-binlog` option for `ndb_restore`. When used, this option prevents information being written to SQL node binary logs from the restoration of a cluster backup. ([Bug#30452](#))

Bugs fixed:

- **Cluster API: MySQL Cluster:** Changing the system time on data nodes could cause MGM API applications to hang and the data nodes to crash. ([Bug#35607](#))
- **MySQL Cluster:** In certain rare situations, `ndb_size.pl` could fail with the error `CAN'T USE STRING ("VALUE") AS A HASH REF WHILE "STRICT REFS" IN USE`. ([Bug#43022](#))
- **MySQL Cluster:** Failure of a data node could sometimes cause `mysqld` to crash. ([Bug#37628](#))
- **MySQL Cluster:** If subscription was terminated while a node was down, the epoch was not properly acknowledged by that node. ([Bug#37442](#))
- **MySQL Cluster:** In rare circumstances, a connection followed by a disconnection could give rise to a “stale” connection where the connection still existed but was not seen by the transporter. ([Bug#37338](#))
- **MySQL Cluster:** Under some circumstances, a failed `CREATE TABLE` could mean that subsequent `CREATE TABLE` statements caused node failures. ([Bug#37092](#))
- **MySQL Cluster:** A fail attempt to create an `NDB` table could in some cases lead to resource leaks or cluster failures. ([Bug#37072](#))
- **MySQL Cluster:** Checking of API node connections was not efficiently handled. ([Bug#36843](#))
- **MySQL Cluster:** Attempting to delete a non-existent row from a table containing a `TEXT` or `BLOB` column within a transaction caused the transaction to fail. ([Bug#36756](#))

See also [Bug#36851](#)

- **MySQL Cluster:** Queries against `NDBCLUSTER` tables were cached only if `AUTOCOMMIT` was in use. ([Bug#36692](#))
- **MySQL Cluster:** `SET GLOBAL ndb_extra_logging` caused `mysqld` to crash. ([Bug#36547](#))
- **MySQL Cluster:** If the combined total of tables and indexes in the cluster was greater than 4096, issuing `START BACKUP` caused data nodes to fail. ([Bug#36044](#))
- **MySQL Cluster:** When more than one SQL node connected to the cluster at the same time, creation of the `mysql.ndb_schema` table failed on one of them with an explicit `TABLE EXISTS` error, which was not necessary. ([Bug#35943](#))
- **MySQL Cluster:** `mysqld` failed to start after running `mysql_upgrade`. ([Bug#35708](#))
- **MySQL Cluster:** If an error occurred while executing a statement involving a `BLOB` or `TEXT` column of an `NDB` table, a memory leak could result. ([Bug#35593](#))
- **MySQL Cluster:** It was not possible to determine the value used for the `--ndb-cluster-connection-pool` option in the `mysql` client. Now this value is reported as a system status variable. ([Bug#35573](#))
- **MySQL Cluster:** The `ndb_waiter` utility wrongly calculated timeouts. ([Bug#35435](#))
- **MySQL Cluster:** Where column values to be compared in a query were of the `VARCHAR` or `VARBINARY` types, `NDB-CLUSTER` passed a value padded to the full size of the column, which caused unnecessary data to be sent to the data nodes. This also had the effect of wasting CPU and network bandwidth, and causing condition pushdown to be disabled where it could (and should) otherwise have been applied. ([Bug#35393](#))
- **MySQL Cluster:** `ndb_restore` incorrectly handled some datatypes when applying log files from backups. ([Bug#35343](#))
- **MySQL Cluster:** In some circumstances, a stopped data node was handled incorrectly, leading to redo log space being exhausted following an initial restart of the node, or an initial or partial restart of the cluster (the wrong CGI might be used in such cases). This could happen, for example, when a node was stopped following the creation of a new table, but before a new LCP could be executed. ([Bug#35241](#))
- **MySQL Cluster:** `SELECT ... LIKE ...` queries yielded incorrect results when used on `NDB` tables. As part of this fix, condition pushdown of such queries has been disabled; re-enabling it is expected to be done as part of a later, permanent fix for this issue. ([Bug#35185](#))
- **MySQL Cluster:** `ndb_mgmd` reported errors to `STDOUT` rather than to `STDERR`. ([Bug#35169](#))
- **MySQL Cluster:** Nested multi-range reads failed when the second multi-range read released the first read's unprocessed operations, sometimes leading to a SQL node crash. ([Bug#35137](#))
- **MySQL Cluster:** In some situations, a problem with synchronizing checkpoints between nodes could cause a system restart or a node restart to fail with `ERROR 630 DURING RESTORE OF TX`. ([Bug#34756](#))

- **MySQL Cluster:** When a secondary index on a `DECIMAL` column was used to retrieve data from an `NDB` table, no results were returned even if the target table had a matched value in the column that was defined with the secondary index. (Bug#34515)
  - **MySQL Cluster:** An `UPDATE` on an `NDB` table that set a new value for a unique key column could cause subsequent queries to fail. (Bug#34208)
  - **MySQL Cluster:** If a data node in one node group was placed in the “not started” state (using `node_id RESTART -n`), it was not possible to stop a data node in a different node group. (Bug#34201)
  - **MySQL Cluster:** If an API node disconnected and then reconnected during Start Phase 8, then the connection could be “blocked” — that is, the `QMGR` kernel block failed to detect that the API node was in fact connected to the cluster, causing issues with the `NDB` Subscription Manager (`SUMA`).
  - **MySQL Cluster:** `NDB` error 1427 (`API NODE DIED, WHEN SUB_START_REQ REACHED NODE`) was incorrectly classified as a schema error rather than a temporary error.
  - **MySQL Cluster:** When dropping a table failed for any reason (such as when in single user mode) then the corresponding `.ndb` file was still removed.
  - **Replication:** When flushing tables, there were a slight chance that the flush occurred between the processing of one table map event and the next. Since the tables were opened one by one, subsequent locking of tables would cause the slave to crash. This problem was observed when replicating `NDBCLUSTER` or `InnoDB` tables, when executing multi-table updates, and when a trigger or a stored routine performed an (additional) insert on a table so that two tables were effectively being inserted into in the same statement. (Bug#36197)
  - **Cluster Replication:** Performing `SELECT ... FROM mysql.ndb_apply_status` before the `mysqld` process had connected to the cluster failed, and caused this table never to be created. (Bug#36123)
  - **Cluster Replication:** In some cases, when updating only one or some columns in a table, the complete row was written to the binary log instead of only the updated column or columns, even when `ndb_log_updated_only` was set to 1. (Bug#35208)
  - **Cluster API:** Creating a table on an SQL node, then starting an `NDB` API application that listened for events from this table, then dropping the table from an SQL node, prevented data node restarts. (Bug#37279)
  - **Cluster API:** When some operations succeeded and some failed following a call to `NdbTransaction::execute(Commit, AO_IgnoreOnError)`, a race condition could cause spurious occurrences of `NDB` API Error 4011 (`INTERNAL ERROR`). (Bug#37158)
  - **Cluster API:** Ordered index scans were not pruned correctly where a partitioning key was specified with an EQ-bound. (Bug#36950)
  - **Cluster API:** When an insert operation involving `BLOB` data was attempted on a row which already existed, no duplicate key error was correctly reported and the transaction is incorrectly aborted. In some cases, the existing row could also become corrupted. (Bug#36851)
- See also Bug#26756
- **Cluster API:** Attempting to pass a nonexistent column name to the `equal()` and `setValue()` methods of `NdbOperation` caused `NDB` API applications to crash. Now the column name is checked, and an error is returned in the event that the column is not found. (Bug#33747)
  - **Cluster API:** Relocation errors were encountered when trying to compile `NDB` API applications on a number of platforms, including 64-bit Linux. As a result, `libmysys`, `libmystrings`, and `libdbug` have been changed from normal libraries to “noinst” `libtool` helper libraries. They are no longer installed as separate libraries; instead, all necessary symbols from these are added directly to `libndbclient`. This means that `NDB` API programs now need to be linked only using `-lndbclient`. (Bug#29791)
  - **Cluster API:** `mgmapi.h` contained constructs which only worked in C++, but not in C. (Bug#27004)

### 19.17.2.2. Changes in MySQL Cluster NDB 6.2.15 (5.1.23-ndb-6.2.15) (22 May 2008)

This is re-release of MySQL Cluster NDB 6.2.14 providing binaries for supported platforms. For more information, see [Section 19.17.2.3, “Changes in MySQL Cluster NDB 6.2.14 \(5.1.23-ndb-6.2.14\) \(05 March 2008\)”](#).

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

### 19.17.2.3. Changes in MySQL Cluster NDB 6.2.14 (5.1.23-ndb-6.2.14) (05 March 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.5, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

## Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** Added the `MaxBufferedEpochs` data node configuration parameter, which controls the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect.  
  
See [Section 19.3.4.5, “Defining Data Nodes”](#), for more information.
- **Replication:** Introduced the `slave_exec_mode` system variable to control whether idempotent or strict mode is used for replication conflict resolution. Idempotent mode suppresses duplicate-key, no-key-found, and some other errors, and is needed for circular replication, multi-master replication, and some other complex replication setups when using MySQL Cluster. Strict mode is the default. ([Bug#31609](#))
- **Cluster Replication:** `RESET MASTER` now uses `TRUNCATE` rather than `DELETE` to clear the `mysql.ndb_binlog_index` table. This improves the performance of the statement and is less likely to leave the table in a fragmented state. ([Bug#34356](#))
- Formerly, when the MySQL server crashed, the generated stack dump was numeric and required external tools to properly resolve the names of functions. This is not very helpful to users having a limited knowledge of debugging techniques. In addition, the generated stack trace contained only the names of functions and was formatted differently for each platform due to different stack layouts.

Now it is possible to take advantage of newer versions of the GNU C Library provide a set of functions to obtain and manipulate stack traces from within the program. On systems that use the ELF binary format, the stack trace contains important information such as the shared object where the call was generated, an offset into the function, and the actual return address. Having the function name also makes possible the name demangling of C++ functions.

The library generates meaningful stack traces on the following platforms: i386, x86\_64, PowerPC, IA64, Alpha, and S390. On other platforms, a numeric stack trace is still produced, and the use of the `resolve_stack_dump` utility is still required. ([Bug#31891](#))

- `mysqltest` now has `mkdir` and `rmdir` commands for creating and removing directories. ([Bug#31004](#))
- Added the `Uptime_since_flush_status` status variable, which indicates the number of seconds since the most recent `FLUSH STATUS` statement. (From Jeremy Cole) ([Bug#24822](#))

Bugs fixed:

- **Important Change: Replication:** When the master crashed during an update on a transactional table while in `AUTOCOMMIT` mode, the slave failed. This fix causes every transaction (including `AUTOCOMMIT` transactions) to be recorded in the binlog as starting with a `BEGIN` and ending with a `COMMIT` or `ROLLBACK`. ([Bug#26395](#))
- **Replication: Important Note:** Network timeouts between the master and the slave could result in corruption of the relay log. This fix rectifies a long-standing replication issue when using unreliable networks, including replication over wide area networks such as the Internet. If you experience reliability issues and see many `YOU HAVE AN ERROR IN YOUR SQL SYNTAX` errors on replication slaves, we strongly recommend that you upgrade to a MySQL version which includes this fix. ([Bug#26489](#))
- **Replication:** When the Windows version of `mysqlbinlog` read 4.1 binlogs containing `LOAD DATA INFILE` statements, it output backslashes as path separators, causing problems for client programs expecting forward slashes. In such cases, it now converts `\\` to `/` in directory paths. ([Bug#34355](#))
- **Replication:** `SHOW SLAVE STATUS` failed when slave I/O was about to terminate. ([Bug#34305](#))
- **Replication:** `mysqlbinlog` from a 5.1 or later MySQL distribution could not read binary logs generated by a 4.1 server when

the logs contained `LOAD DATA INFILE` statements. (Bug#34141)

This regression was introduced by Bug#32407

- **Replication:** A `CREATE USER`, `DROP USER`, or `RENAME USER` statement that fails on the master, or that is a duplicate of any of these statements, is no longer written to the binlog; previously, either of these occurrences could cause the slave to fail. (Bug#33862)

See also Bug#29749

- **Replication:** `mysqlbinlog` failed to release all of its memory after terminating abnormally. (Bug#33247)
- **Replication:** The error message generated due to lack of a default value for an extra column was not sufficiently informative. (Bug#32971)
- **Replication:** When a user variable was used inside an `INSERT` statement, the corresponding binlog event was not written to the binlog correctly. (Bug#32580)
- **Replication:** When using row-based replication, deletes from a table with a foreign key constraint failed on the slave. (Bug#32468)
- **Replication:** SQL statements containing comments using `--` syntax were not replayable by `mysqlbinlog`, even though such statements replicated correctly. (Bug#32205)
- **Replication:** When using row-based replication from a master running MySQL 5.1.21 or earlier to a slave running 5.1.22 or later, updates of integer columns failed on the slave with `ERROR IN UNKNOWN EVENT: ROW APPLICATION FAILED`. (Bug#31583)

This regression was introduced by Bug#21842

- **Replication:** Replicating write, update, or delete events from a master running MySQL 5.1.15 or earlier to a slave running 5.1.16 or later caused the slave to crash. (Bug#31581)
- **Replication:** When using row-based replication, the slave stopped when attempting to delete non-existent rows from a slave table without a primary key. In addition, no error was reported when this occurred. (Bug#31552)
- **Replication:** Issuing a `DROP VIEW` statement caused replication to fail if the view did not actually exist. (Bug#30998)
- **Replication:** Setting `server_id` did not update its value for the current session. (Bug#28908)
- **Replication:** Slaves running MySQL 5.1.18 and later could not read binary logs from older versions of the server. (Bug#27779, Bug#32434)

This regression was introduced by Bug#22583

- **Cluster Replication:** The `--ndb-wait-connected` option caused the server to wait for a partial connection plus an additional 3 seconds for a complete connection to the cluster. This could lead to issues with setting up the binary log. (Bug#34757)
- Use of stored functions in the `WHERE` clause for `SHOW OPEN TABLES` caused a server crash. (Bug#34166)
- Large unsigned integers were improperly handled for prepared statements, resulting in truncation or conversion to negative numbers. (Bug#33798)
- The server crashed when executing a query that had a subquery containing an equality `X=Y` where `Y` referred to a named select list expression from the parent select. The server crashed when trying to use the `X=Y` equality for `ref`-based access. (Bug#33794)
- The `UPDATE` statement allowed `NULL` to be assigned to `NOT NULL` columns (the default data type value was assigned). An error occurs now. (Bug#33699)
- `ORDER BY ... DESC` sorts could produce misordered results. (Bug#33697)
- The server could crash when `REPEAT` or another control instruction was used in conjunction with labels and a `LEAVE` instruction. (Bug#33618)
- `SET GLOBAL myisam_max_sort_file_size=DEFAULT` set `myisam_max_sort_file_size` to an incorrect value. (Bug#33382)

See also Bug#31177

- Granting the `UPDATE` privilege on one column of a view caused the server to crash. (Bug#33201)
  - For `DECIMAL` columns used with the `ROUND(X,D)` or `TRUNCATE(X,D)` function with a non-constant value of `D`, adding an `ORDER BY` for the function result produced misordered output. (Bug#33143)
- See also Bug#33402, Bug#30617
- The `SHOW ENGINE INNODB STATUS` and `SHOW ENGINE INNODB MUTEX` statements incorrectly required the `SUPER` privilege rather than the `PROCESS` privilege. (Bug#32710)
  - Tables in the `mysql` database that stored the current `sql_mode` value as part of stored program definitions were not updated with newer mode values (`NO_ENGINE_SUBSTITUTION`, `PAD_CHAR_TO_FULL_LENGTH`). This causes various problems defining stored programs if those modes were included in the current `sql_mode` value. (Bug#32633)
  - `ROUND(X,D)` or `TRUNCATE(X,D)` for non-constant values of `D` could crash the server if these functions were used in an `ORDER BY` that was resolved using `filesort`. (Bug#30889)
  - Resetting the query cache by issuing a `SET GLOBAL query_cache_size=0` statement caused the server to crash if it concurrently was saving a new result set to the query cache. (Bug#30887)
  - Replication of `LOAD DATA INFILE` could fail when `read_buffer_size` was larger than `max_allowed_packet`. (Bug#30435)
  - The `Table_locks_waited` variable was not incremented in the cases that a lock had to be waited for but the waiting thread was killed or the request was aborted. (Bug#30331)
  - The `Com_create_function` status variable was not incremented properly. (Bug#30252)
  - `mysqld` displayed the `--enable-pstack` option in its help message even if MySQL was configured without `--with-pstack`. (Bug#29836)
  - Replication crashed with the `NDB` storage engine when `mysqld` was started with `--character-set-server=ucs2`. (Bug#29562)
  - Views were treated as insertable even if some base table columns with no default value were omitted from the view definition. (This is contrary to the condition for insertability that a view must contain all columns in the base table that do not have a default value.) (Bug#29477)
  - Previously, the parser accepted the ODBC `{ OJ ... LEFT OUTER JOIN ... }` syntax for writing left outer joins. The parser now allows `{ OJ ... }` to be used to write other types of joins, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax. (Bug#28317)
  - The parser rules for the `SHOW PROFILE` statement were revised to work with older versions of `bison`. (Bug#27433)
  - `resolveip` failed to produce correct results for hostnames that begin with a digit. (Bug#27427)
  - `mysqlcheck -A -r` did not correctly identify all tables that needed repairing. (Bug#25347)
  - `InnoDB` exhibited thread thrashing with more than 50 concurrent connections under an update-intensive workload. (Bug#22868)
  - Warnings for deprecated syntax constructs used in stored routines make sense to report only when the routine is being created, but they were also being reported when the routine was parsed for loading into the execution cache. Now they are reported only at routine creation time. (Bug#21801)
  - `CREATE ... SELECT` did not always set `DEFAULT` column values in the new table. (Bug#21380)
  - If a `SELECT` calls a stored function in a transaction, and a statement within the function fails, that statement should roll back. Furthermore, if `ROLLBACK` is executed after that, the entire transaction should be rolled back. Before this fix, the failed statement did not roll back when it failed (even though it might ultimately get rolled back by a `ROLLBACK` later that rolls back the entire transaction). (Bug#12713)
- See also Bug#34655

#### 19.17.2.4. Changes in MySQL Cluster NDB 6.2.13 (5.1.23-ndb-6.2.13) (22 February 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.5, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. ([Bug#34702](#))

### 19.17.2.5. Changes in MySQL Cluster NDB 6.2.12 (5.1.23-ndb-6.2.12) (12 February 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.5, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Beginning with this version, MySQL Cluster NDB 6.3.x releases once again include the [InnoDB](#) storage engine. In order to enable [InnoDB](#), you must configure the build using `--with-innodb`.

Bugs fixed:

- **MySQL Cluster:** Upgrades of a cluster using while a [DataMemory](#) setting in excess of 16 GB caused data nodes to fail. ([Bug#34378](#))
- **MySQL Cluster:** Performing many SQL statements on [NDB](#) tables while in [AUTOCOMMIT](#) mode caused a memory leak in `mysqld`. ([Bug#34275](#))
- **MySQL Cluster:** In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. ([Bug#34260](#))
- **MySQL Cluster:** Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. ([Bug#34216](#))
- **MySQL Cluster:** When configured with [NDB](#) support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. ([Bug#34169](#))
- **MySQL Cluster:** The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. ([Bug#34160](#))
- **MySQL Cluster:** Extremely long [SELECT](#) statements (where the text of the statement was in excess of 50000 characters) against [NDB](#) tables returned empty results. ([Bug#34107](#))
- **MySQL Cluster:** Statements executing multiple inserts performed poorly on [NDB](#) tables having [AUTO\\_INCREMENT](#) columns. ([Bug#33534](#))
- **MySQL Cluster:** The `ndb_waiter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. ([Bug#32025](#))

See also [Bug#32023](#)

- **MySQL Cluster:** Transaction atomicity was sometimes not preserved between reads and inserts under high loads. (Bug#31477)
- **MySQL Cluster:** Having tables with a great many columns could cause Cluster backups to fail. (Bug#30172)
- **Cluster Replication: Disk Data:** Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. (Bug#34118)
- **Disk Data:** Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. (Bug#33619)
- **Cluster Replication:** Setting `--replicate-ignore-db=mysql` caused the `mysql.ndb_apply_status` table not to be replicated, breaking Cluster Replication. (Bug#28170)

### 19.17.2.6. Changes in MySQL Cluster NDB 6.2.11 (5.1.23-ndb-6.2.11) (28 January 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.5, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster API: Important Change:** Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See [The `Ndb\_logevent\_type` Type](#), for more information about `NDB_LE_MemoryUsage`. (Bug#30271)

Bugs fixed:

- **MySQL Cluster:** High numbers of insert operations, delete operations, or both could cause NDB error 899 (`ROWID ALREADY ALLOCATED`) to occur unnecessarily. (Bug#34033)
- **MySQL Cluster:** A periodic failure to flush the send buffer by the NDB TCP transporter could cause a unnecessary delay of 10 ms between operations. (Bug#34005)
- **MySQL Cluster:** A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. (Bug#33793)
- **MySQL Cluster:** Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. (Bug#33739)
- **MySQL Cluster:** The server failed to reject properly the creation of an NDB table having an unindexed `AUTO_INCREMENT` column. (Bug#30417)
- **MySQL Cluster:** Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE` statement on an NDB table failed with NDB error 4350 (`TRANSACTION ALREADY ABORTED`). (Bug#29851)
- **MySQL Cluster:** The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. (Bug#28647)
- **MySQL Cluster:** It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum allowed value. (Bug#28298)
- **Cluster Replication:** `ndb_restore -e` restored excessively large values to the `ndb_apply_status` table's `epoch` column when restoring to a MySQL Cluster version supporting Micro-GCPs from an older version that did not support these.

A workaround when restoring to MySQL Cluster releases supporting micro-GCPs previous to MySQL Cluster NDB 6.3.8 is to perform a 32-bit shift on the `epoch` column values to reduce them to their proper size. (Bug#33406)

- **Cluster API:** Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` equal to 0. (Bug#33895)
- **Cluster API:** When reading a `BIT(64)` value using `NdbOperation::getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. (Bug#33750)

### 19.17.2.7. Changes in MySQL Cluster NDB 6.2.10 (5.1.23-ndb-6.2.10) (19 December 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.5, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Important Change: MySQL Cluster:** `AUTO_INCREMENT` columns had the following problems when used in NDB tables:
  - The `AUTO_INCREMENT` counter was not updated correctly when such a column was updated.
  - `AUTO_INCREMENT` values were not prefetched beyond statement boundaries.
  - `AUTO_INCREMENT` values were not handled correctly with `INSERT IGNORE` statements.
  - After being set, `ndb_autoincrement_prefetch_sz` showed a value of 1, regardless of the value it had actually been set to.  
As part of this fix, the behavior of `ndb_autoincrement_prefetch_sz` has changed. Setting this to less than 32 no longer has any effect on prefetching within statements (where IDs are now always obtained in batches of 32 or more), but only between statements. The default value for this variable has also changed, and is now 1. (Bug#25176, Bug#31956, Bug#32055)
- **Partitioning: MySQL Cluster:** When partition pruning on an NDB table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC, MAX()` to be handled incorrectly, and similar problems. (Bug#33061)
- **MySQL Cluster:** When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. (Bug#33237)
- **MySQL Cluster:** When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. (Bug#32922)
- **MySQL Cluster:** Under some conditions, performing an `ALTER TABLE` on an NDBCLUSTER table failed with a `TABLE IS FULL` error, even when only 25% of `DataMemory` was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). (Bug#32670)

### 19.17.2.8. Changes in MySQL Cluster NDB 6.2.9 (5.1.22-ndb-6.2.9) (22 November 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes

and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.6, “Changes in MySQL 5.1.22 \(24 September 2007: Release Candidate\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** Added the `ndb_mgm` client command `DUMP 8011`, which dumps all subscribers to the cluster log. See `DUMP 8011`, for more information.

Bugs fixed:

- **MySQL Cluster:** A local checkpoint could sometimes be started before the previous LCP was restorable from a global checkpoint. ([Bug#32519](#))
- **MySQL Cluster:** High numbers of API nodes on a slow or congested network could cause connection negotiation to time out prematurely, leading to the following issues:
  - Excessive retries
  - Excessive CPU usage
  - Partially connected API nodes ([Bug#32359](#))
- **MySQL Cluster:** The failure of a master node could lead to subsequent failures in local checkpointing. ([Bug#32160](#))
- **MySQL Cluster:** Adding a new `TINYTEXT` column to an `NDB` table which used `COLUMN_FORMAT = DYNAMIC`, and when binary logging was enabled, caused all cluster `mysqld` processes to crash. ([Bug#30213](#))
- **MySQL Cluster:** After adding a new column of one of the `TEXT` or `BLOB` types to an `NDB` table which used `COLUMN_FORMAT = DYNAMIC`, it was no longer possible to access or drop the table using SQL. ([Bug#30205](#))
- **MySQL Cluster:** A restart of the cluster failed when more than 1 REDO phase was in use. ([Bug#22696](#))
- **Cluster Replication:** Under certain conditions, the slave stopped processing relay logs. This resulted in the logs never being cleared and the slave eventually running out of disk space. ([Bug#31958](#))
- **Cluster Replication:** Where a table being replicated had a `TEXT` or `BLOB` column, an `UPDATE` on the master that did not refer explicitly to this column in the `WHERE` clause stopped the SQL thread on the slave with `ERROR IN WRITE_ROWS EVENT: ROW APPLICATION FAILED. GOT ERROR 4288 'BLOB HANDLE FOR COLUMN NOT AVAILABLE' FROM NDBCLUSTER.` ([Bug#30674](#))

## 19.17.2.9. Changes in MySQL Cluster NDB 6.2.8 (5.1.22-ndb-6.2.8) (08 November 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.6, “Changes in MySQL 5.1.22 \(24 September 2007: Release Candidate\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Note:** MySQL Cluster NDB 6.2 and 6.3 source archives are now available in separate commercial and GPL versions. Due to licensing concerns, previous MySQL Cluster NDB 6.2 and 6.3 source archives were removed from the FTP site.

Bugs fixed:

- **MySQL Cluster:** In a cluster running in diskless mode and with arbitration disabled, the failure of a data node during an insert operation caused other data node to fail. (Bug#31980)
- **MySQL Cluster:** An insert or update with combined range and equality constraints failed when run against an NDB table with the error `GOT UNKNOWN ERROR FROM NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. (Bug#31874)
- **MySQL Cluster:** An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in NDB tables. (Bug#31810)
- **MySQL Cluster:** The NDB storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. (Bug#31761)
- **MySQL Cluster:** Following an upgrade, `ndb_mgmd` would fail with an `ArbitrationError`. (Bug#31690)
- **MySQL Cluster:** The NDB management client command `node_id REPORT MEMORY` provided no output when `node_id` was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node node_id: is not a data node`. (Bug#29485)
- **MySQL Cluster:** Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. (Bug#26450)
- **MySQL Cluster:** `UPDATE IGNORE` could sometimes fail on NDB tables due to the use of uninitialized data when checking for duplicate keys to be ignored. (Bug#25817)
- **Cluster Replication:** A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. (Bug#31701)
- **Cluster Replication:** When the master `mysqld` crashed or was restarted, no `LOST_EVENTS` entry was made in the binlog. (Bug#31484)

See also Bug#21494

### 19.17.2.10. Changes in MySQL Cluster NDB 6.2.7 (5.1.22-ndb-6.2.7) (10 October 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.6, “Changes in MySQL 5.1.22 \(24 September 2007: Release Candidate\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication:** A new configuration parameter `TimeBetweenEpochsTimeout` allows a timeout to be set for time between epochs. For more information, see [Section 19.3.4.5, “Defining Data Nodes”](#). (Bug#31276)
- Additional checks were implemented to catch unsupported online `ALTER TABLE` operations. Currently it is not possible to reorder columns or to change the storage engine used for a table via online `ALTER`.

Some redundant checks made during online creation of indexes were removed.

Bugs fixed:

- **MySQL Cluster:** It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. (Bug#31525)
- **MySQL Cluster:** NDB tables having names containing non-alphanumeric characters (such as “`$`”) were not discovered cor-

rectly. (Bug#31470)

- **MySQL Cluster:** A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. (Bug#31257)
- **MySQL Cluster:** Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. (Bug#30379)
- **MySQL Cluster:** In some cases, the cluster management server logged entries multiple times following a restart of `mgmd`. (Bug#29565)
- **MySQL Cluster:** `ndb_mgm --help` did not display any information about the `-a` option. (Bug#29509)
- **MySQL Cluster:** The cluster log was formatted inconsistently and contained extraneous newline characters. (Bug#25064)
- Online `ALTER` operations involving a column whose data type has an implicit default value left behind temporary `.FRM` files, causing subsequent `DROP DATABASE` statements to fail. (Bug#31097)
- Transactions were committed prematurely when `LOCK TABLE` and `SET AUTOCOMMIT=OFF` were used together. (Bug#30996)
- A cluster restart could sometimes fail due to an issue with table IDs. (Bug#30975)
- The `mysqld_safe` script contained a syntax error. (Bug#30624)

### 19.17.2.11. Changes in MySQL Cluster NDB 6.2.6 (5.1.22-ndb-6.2.6) (20 September 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.6, “Changes in MySQL 5.1.22 \(24 September 2007: Release Candidate\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** Mapping of NDB error codes to MySQL storage engine error codes has been improved. (Bug#28423)

Bugs fixed:

- **Partitioning: MySQL Cluster:** `EXPLAIN PARTITIONS` reported partition usage by queries on NDB tables according to the standard MySQL hash function than the hash function used in the NDB storage engine. (Bug#29550)
- **MySQL Cluster:** Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. (Bug#29674)
- **MySQL Cluster:** The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. (Bug#27683)
- **MySQL Cluster:** Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATETIME` columns. (Bug#27543, Bug#30024)
- **MySQL Cluster:** An insufficiently descriptive and potentially misleading Error 4006 (`CONNECT FAILURE - OUT OF CONNECTION OBJECTS . . .`) was produced when either of the following two conditions occurred:
  1. There were no more transaction records in the transaction coordinator
  2. an `Ndb` object in the NDB API was initialized with insufficient parallelism
 Separate error messages are now generated for each of these two cases. (Bug#11313)

- **Cluster API:** An `Ndb` object in the NDB API was initialized with insufficient parallelism.
- For micro-GCPs, fixed the assignment of “fake” CGI events so that they do not cause buckets to be sent out of order. Now, when assigning a GCI to a non-GCI event (that is, creating a pseudo-GCI or “fake” CGI), the GCI that is to arrive is always initiated, even if no known GCI exists, which could occur in the event of a node failure. (Bug#30884)
- When an NDB event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. (Bug#30877)
- There were no more transaction records in the transaction coordinator

### 19.17.2.12. Changes in MySQL Cluster NDB 6.2.5 (5.1.22-ndb-6.2.5) (06 September 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.6, “Changes in MySQL 5.1.22 \(24 September 2007: Release Candidate\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** The following improvements have been made in the `ndb_size.pl` utility:
  - The script can now be used with multiple databases; lists of databases and tables can also be excluded from analysis.
  - Schema name information has been added to index table calculations.
  - The database name is now an optional parameter, the exclusion of which causes all databases to be examined.
  - If selecting from `INFORMATION_SCHEMA` fails, the script now attempts to fall back to `SHOW TABLES`.
  - A `--real_table_name` option has been added; this designates a table to handle unique index size calculations.
  - The report title has been amended to cover cases where more than one database is being analyzed.

Support for a `--socket` option was also added.

For more information, see [Section 19.10.15, “ndb\\_size.pl — NDBCLUSTER Size Requirement Estimator”](#). (Bug#28683, Bug#28253)

- **MySQL Cluster:** `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed online for NDB tables, as well as online renaming of tables and columns for NDB and MyISAM tables — that is, without copying or locking of the affected tables — using `ALTER ONLINE TABLE`.

Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

See [Section 12.1.4, “ALTER TABLE Syntax”](#), [Section 12.1.7, “CREATE INDEX Syntax”](#), and [Section 12.1.13, “DROP INDEX Syntax”](#), for more information.

- **MySQL Cluster:** It is now possible to control whether fixed-width or variable-width storage is used for a given column of an NDB table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

It is also possible to control whether a given column of an NDB table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see [Section 12.1.10, “CREATE TABLE Syntax”](#).

- **MySQL Cluster:** A new cluster management server startup option `--bind-address` makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see [Section 19.6.5.2, “Command Options for ndb\\_mgmd”](#).
- **Cluster Replication: Replication:** The protocol for handling global checkpoints has been changed. It is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` configuration parameter. This improves the reliability and performance of MySQL Cluster Replication.

GCPs handled using the new protocol are sometimes referred to as “micro-GCPs”.

For more information, see [TimeBetweenEpochs](#) .

Bugs fixed:

- **MySQL Cluster:** When handling `BLOB` columns, the addition of read locks to the lock queue was not handled correctly. ([Bug#30764](#))
- **MySQL Cluster:** Discovery of `NDB` tables did not work correctly with `INFORMATION_SCHEMA`. ([Bug#30667](#))
- **MySQL Cluster:** A filesystem close operation could fail during a node or system restart. ([Bug#30646](#))
- **MySQL Cluster:** Using the `--ndb-cluster-connection-pool` option for `mysqld` caused DDL statements to be executed twice. ([Bug#30598](#))
- **MySQL Cluster:** `ndb_size.pl` failed on tables with `FLOAT` columns whose definitions included commas (for example, `FLOAT(6,2)`). ([Bug#29228](#))
- **MySQL Cluster:** Reads on `BLOB` columns were not locked when they needed to be to guarantee consistency. ([Bug#29102](#))

See also [Bug#31482](#)

- **MySQL Cluster:** A query using joins between several large tables and requiring unique index lookups failed to complete, eventually returning `UNKNOWN ERROR` after a very long period of time. This occurred due to inadequate handling of instances where the Transaction Coordinator ran out of `TransactionBufferMemory`, when the cluster should have returned `NDB` error code 4012 (`REQUEST NDBD TIME-OUT`). ([Bug#28804](#))
- **MySQL Cluster:** An attempt to perform a `SELECT ... FROM INFORMATION_SCHEMA.TABLES` whose result included information about `NDB` tables for which the user had no privileges crashed the MySQL Server on which the query was performed. ([Bug#26793](#))
- **Cluster Replication:** Cluster replication did not handle large `VARCHAR` columns correctly. ([Bug#29904](#))
- **Cluster Replication:** An issue with the `mysql.ndb_apply_status` table could cause `NDB` schema autodiscovery to fail in certain rare circumstances. ([Bug#20872](#))
- **Cluster API:** A call to `CHECK_TIMEDOUT_RET()` in `mgmapi.cpp` should have been a call to `DBG_CHECK_TIMEDOUT_RET()`. ([Bug#30681](#))

### 19.17.2.13. Changes in MySQL Cluster NDB 6.2.4 (5.1.19-ndb-6.2.4) (04 July 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see [Section C.1.9, “Changes in MySQL 5.1.19 \(25 May 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** When restarting a data node, queries could hang during that node's start phase 5, and continue only after the

node had entered phase 6. ([Bug#29364](#))

- **MySQL Cluster:** Replica redo logs were inconsistently handled during a system restart. ([Bug#29354](#))
- **Disk Data:** Performing Disk Data schema operations during a node restart could cause forced shutdowns of other data nodes. ([Bug#29501](#))
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. ([Bug#28720](#))
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. ([Bug#28642](#))
- Batching of transactions was not handled correctly in some cases. ([Bug#29525](#))

#### 19.17.2.14. Changes in MySQL Cluster NDB 6.2.3 (5.1.19-ndb-6.2.3) (02 July 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see [Section C.1.10](#), “Changes in MySQL 5.1.18 (08 May 2007)”).

##### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. ([Bug#29364](#))
- **MySQL Cluster:** Replica redo logs were inconsistently handled during a system restart. ([Bug#29354](#))
- **Disk Data:** Performing Disk Data schema operations during a node restart could cause forced shutdowns of other data nodes. ([Bug#29501](#))
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. ([Bug#28720](#))
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. ([Bug#28642](#))
- Batching of transactions was not handled correctly in some cases. ([Bug#29525](#))

#### 19.17.2.15. Changes in MySQL Cluster NDB 6.2.2 (5.1.18-ndb-6.2.2) (07 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see [Section C.1.10](#), “Changes in MySQL 5.1.18 (08 May 2007)”).

##### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See `DUMP 2350`, `DUMP 2352`, and `DUMP 2550`, for more information.
- **MySQL Cluster:** Added the `mysqld` option `--ndb-cluster-connection-pool` that allows a single MySQL server to

use multiple connections to the cluster. This allows for scaling out using multiple MySQL clients per SQL node instead of or in addition to using multiple SQL nodes with the cluster.

For more information about this option, see [Section 19.4, “MySQL Cluster Options and Variables”](#).

### 19.17.2.16. Changes in MySQL Cluster NDB 6.2.1 (5.1.18-ndb-6.2.1) (30 April 2007)

This is a Beta development release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.2 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see [Section C.1.10, “Changes in MySQL 5.1.18 \(08 May 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** Multiple operations involving deletes followed by reads were not handled correctly.

#### Note

This issue could also affect MySQL Cluster Replication.

([Bug#28276](#))

- **Cluster API:** Using `NdbBlob::writeData()` to write data in the middle of an existing blob value (that is, updating the value) could overwrite some data past the end of the data to be changed. ([Bug#27018](#))
- Incorrect handling of fragmentation in a node takeover during a restart could cause stale data to be copied to the starting node, leading eventually to failure of the node. ([Bug#27434](#))
- An incorrect assertion was made when sending a `TCKEYFAILREF` or `TCKEYCONF` message to a failed data node. ([Bug#26814](#))

### 19.17.2.17. Changes in MySQL Cluster NDB 6.2.0 (5.1.16-ndb-6.2.0) (03 March 2007)

This is the first MySQL Cluster NDB 6.2 development release, based on version 6.2 of the `NDBCLUSTER` storage engine.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster>.

This Beta release incorporates bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.16 (see [Section C.1.12, “Changes in MySQL 5.1.16 \(26 February 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** An `--ndb-wait-connected` option has been added for `mysqld`, which causes `mysqld` to wait for the specified amount of time to connect to the cluster before starting to accept MySQL client connections.
- **Cluster API:** The `Ndb::startTransaction()` method now provides an alternative interface for starting a transaction. See `Ndb::startTransaction()`, for more information.
- **Cluster API:** Methods were added to the `Ndb_cluster_connection` class to facilitate iterating over existing `Ndb` objects. See `ndb_cluster_connection::get_next_ndb_object()`, for more information.

- It is now possible to disable arbitration by setting `ArbitrationRank` equal to 0 on all nodes.
- A new `TcpBind_INADDR_ANY` configuration parameter allows data nodes node to bind `INADDR_ANY` instead of a host-name or IP address in the `config.ini` file.
- Memory allocation has been improved on 32-bit architectures that enables using close to 3GB for `DataMemory` and `IndexMemory` combined.

### 19.17.3. Changes in MySQL Cluster NDB 6.1

This section contains change history information for MySQL Cluster releases based on version 6.1 of the `NDBCLUSTER` storage engine.

For an overview of new features added in MySQL Cluster NDB 6.1, see [Section 19.15.2, “Features Added in MySQL Cluster NDB 6.1”](#).

#### 19.17.3.1. Changes in MySQL Cluster NDB 6.1.23 (5.1.15-ndb-6.1.23) (20 November 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. ([Bug#31761](#))
- **Cluster Replication:** Under certain conditions, the slave stopped processing relay logs. This resulted in the logs never being cleared and the slave eventually running out of disk space. ([Bug#31958](#))

#### 19.17.3.2. Changes in MySQL Cluster NDB 6.1.22 (5.1.15-ndb-6.1.22) (19 October 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. ([Bug#31525](#))
- **Cluster Replication:** A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. ([Bug#31701](#))

### 19.17.3.3. Changes in MySQL Cluster NDB 6.1.21 (5.1.15-ndb-6.1.21) (01 October 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. ([Bug#31257](#))
- A cluster restart could sometimes fail due to an issue with table IDs. ([Bug#30975](#))

### 19.17.3.4. Changes in MySQL Cluster NDB 6.1.20 (5.1.15-ndb-6.1.20) (14 September 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Cluster Replication:** Incorrect handling of `INSERT` plus `DELETE` operations with regard to local checkpoints caused data node failures in multi-master replication setups. ([Bug#30914](#))

### 19.17.3.5. Changes in MySQL Cluster NDB 6.1.19 (5.1.15-ndb-6.1.19) (01 August 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** Whenever a TCP send buffer is over 80% full, temporary error 1218 (`SEND BUFFERS OVERLOADED IN NDB KERNEL`) is now returned. See [SendBufferMemory](#) for more information.
- An `INFO` event is now sent if the time between global checkpoints is excessive, or if `DUMP 7901` is issued in the management client.

### 19.17.3.6. Changes in MySQL Cluster NDB 6.1.18 (5.1.15-ndb-6.1.18) (Not released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. ([Bug#29364](#))
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. ([Bug#28720](#))
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. ([Bug#28642](#))
- Storage engine error conditions in row-based replication were not correctly reported to the user. ([Bug#29570](#))

### 19.17.3.7. Changes in MySQL Cluster NDB 6.1.17 (5.1.15-ndb-6.1.17) (03 July 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication:** Batching of updates on cluster replication slaves, enabled using the `--slave-allow-batching` option for `mysqld`.

Bugs fixed:

- **MySQL Cluster:** Replica redo logs were inconsistently handled during a system restart. ([Bug#29354](#))

### 19.17.3.8. Changes in MySQL Cluster NDB 6.1.16 (5.1.15-ndb-6.1.16) (29 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** When a node failed to respond to a `COPY_GCI` signal as part of a global checkpoint, the master node was killed instead of the node that actually failed. ([Bug#29331](#))
- **MySQL Cluster:** An invalid comparison made during `REDO` validation that could lead to an `ERROR WHILE READING REDO LOG` condition. ([Bug#29118](#))
- **MySQL Cluster:** The wrong data pages were sometimes invalidated following a global checkpoint. ([Bug#29067](#))
- **MySQL Cluster:** If at least 2 files were involved in `REDO` invalidation, then file 0 of page 0 was not updated and so pointed to an invalid part of the redo log. ([Bug#29057](#))
- **Disk Data:** When dropping a page, the stack's bottom entry could sometime be left “cold” rather than “hot”, violating the rules for stack pruning. ([Bug#29176](#))

### 19.17.3.9. Changes in MySQL Cluster NDB 6.1.15 (5.1.15-ndb-6.1.15) (20 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** Memory corruption could occur due to a problem in the `DBTUP` kernel block. ([Bug#29229](#))

### 19.17.3.10. Changes in MySQL Cluster NDB 6.1.14 (5.1.15-ndb-6.1.14) (19 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** In the event that two data nodes in the same node group and participating in a GCP crashed before they had written their respective `PO.sysfile` files, `QMGR` could refuse to start, issuing an invalid `INSUFFICIENT_NODES_FOR_RESTART` error instead. (Bug#29167)

### 19.17.3.11. Changes in MySQL Cluster NDB 6.1.13 (5.1.15-ndb-6.1.13) (15 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Read ahead was implemented for backups of Disk Data tables, resulting in a 10 to 15% increase in backup speed of Disk Data tables. (Bug#29099)

### 19.17.3.12. Changes in MySQL Cluster NDB 6.1.12 (5.1.15-ndb-6.1.12) (13 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See `DUMP 2350`, `DUMP 2352`, and `DUMP 2550`.
- Backup dump output was extended to provide more information.

Bugs fixed:

- **MySQL Cluster:** It is now possible to set the maximum size of the allocation unit for table memory using the `MaxAllocate` configuration parameter. (Bug#29044)

### 19.17.3.13. Changes in MySQL Cluster NDB 6.1.11 (5.1.15-ndb-6.1.11) (06 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier

Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change: MySQL Cluster:** The `TimeBetweenWatchdogCheckInitial` configuration parameter was added to allow setting of a separate watchdog timeout for memory allocation during startup of the data nodes. See [Section 19.3.4.5, “Defining Data Nodes”](#), for more information. ([Bug#28899](#))
- **MySQL Cluster:** A new configuration parameter `ODirect` causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.
- It is now possible to set the size of redo log files (fragment log files) using the `FragmentLogFileSize` configuration parameter.

Bugs fixed:

- **MySQL Cluster:** Having large amounts of memory locked caused swapping to disk. ([Bug#28751](#))
- **MySQL Cluster:** LCP files were not removed following an initial system restart. ([Bug#28726](#))
- **Disk Data:** Repeated `INSERT` and `DELETE` operations on a Disk Data table having one or more large `VARCHAR` columns could cause data nodes to fail. ([Bug#20612](#))

## 19.17.3.14. Changes in MySQL Cluster NDB 6.1.10 (5.1.15-ndb-6.1.10) (30 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** A new `times` printout was added in the `ndbd` watchdog thread.
- **MySQL Cluster:** Some unneeded printouts in the `ndbd` out file were removed.
- The names of some log and other files were changed to avoid issues with the `tar` command's 99-character filename limit.

Bugs fixed:

- **MySQL Cluster:** A regression in the heartbeat monitoring code could lead to node failure under high load. This issue affected MySQL 5.1.19 and MySQL Cluster NDB 6.1.10 only. ([Bug#28783](#))
- **MySQL Cluster:** A corrupt schema file could cause a `FILE ALREADY OPEN` error. ([Bug#28770](#))

- **MySQL Cluster:** Setting `InitialNoOpenFiles` equal to `MaxNoOfOpenFiles` caused an error. This was due to the fact that the actual value of `MaxNoOfOpenFiles` as used by the cluster was offset by 1 from the value set in `config.ini`. (Bug#28749)
- **MySQL Cluster:** A race condition could result when non-master nodes (in addition to the master node) tried to update active status due to a local checkpoint (that is, between `NODE_FAILREP` and `COPY_GCIREQ` events). Now only the master updates the active status. (Bug#28717)
- **MySQL Cluster:** A fast global checkpoint under high load with high usage of the redo buffer caused data nodes to fail. (Bug#28653)
- **Disk Data:** When loading data into a cluster following a version upgrade, the data nodes could forcibly shut down due to page and buffer management failures (that is, `ndbrequire` failures in `PGMAN`). (Bug#28525)

### 19.17.3.15. Changes in MySQL Cluster NDB 6.1.9 (5.1.15-ndb-6.1.9) (24 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** When an API node sent more than 1024 signals in a single batch, `NDB` would process only the first 1024 of these, and then hang. (Bug#28443)
- **Disk Data:** The cluster backup process scanned in `ACC` index order, which had bad effects for disk data. (Bug#28593)

### 19.17.3.16. Changes in MySQL Cluster NDB 6.1.8 (5.1.15-ndb-6.1.8) (05 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** Local checkpoint files relating to dropped `NDB` tables were not removed. (Bug#28348)
- **MySQL Cluster:** Repeated insertion of data generated by `mysqldump` into `NDB` tables could eventually lead to failure of the cluster. (Bug#27437)
- **Disk Data:** Extremely large inserts into Disk Data tables could lead to data node failure in some circumstances. (Bug#27942)
- **Cluster API:** In a multi-operation transaction, a delete operation followed by the insertion of an implicit `NULL` failed to overwrite an existing value. (Bug#20535)

- Setting `MaxNoOfTables` very low and relative to `DataMemory` caused `OUT OF MEMORY IN NDB KERNEL` errors when inserting relatively small amounts of data into NDB tables. (Bug#24173)

### 19.17.3.17. Changes in MySQL Cluster NDB 6.1.7 (5.1.15-ndb-6.1.7) (05 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Section C.1.13, “Changes in MySQL 5.1.15 (25 January 2007)”).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server in order for the table to be re-created with the new schema.

See Section 19.11.4, “Cluster Replication Schema and Tables”, for additional information.

Bugs fixed:

- **MySQL Cluster:** The cluster waited 30 seconds instead of 30 milliseconds before reading table statistics. (Bug#28093)
- **MySQL Cluster:** Under certain rare circumstances, `ndbd` could get caught in an infinite loop when one transaction took a read lock and then a second transaction attempted to obtain a write lock on the same tuple in the lock queue. (Bug#28073)
- **MySQL Cluster:** Under some circumstances, a node restart could fail to update the Global Checkpoint Index (GCI). (Bug#28023)
- **MySQL Cluster:** Under certain rare circumstances performing a `DROP TABLE` or `TRUNCATE` on an NDB table could cause a node failure or forced cluster shutdown. (Bug#27581)
- **MySQL Cluster:** Memory usage of a `mysqld` process grew even while idle. (Bug#27560)
- **MySQL Cluster:** Performing a delete followed by an insert during a local checkpoint could cause a `ROWID ALREADY ALLOCATED` error. (Bug#27205)
- **Replication:** Some queries that updated multiple tables were not backed up correctly. (Bug#27748)
- **Cluster Replication: Disk Data:** An issue with replication of Disk Data tables could in some cases lead to node failure. (Bug#28161)
- **Disk Data:** Changes to a Disk Data table made as part of a transaction could not be seen by the client performing the changes until the transaction had been committed. (Bug#27757)
- **Disk Data:** When restarting a data node following the creation of a large number of Disk Data objects (approximately 200 such objects), the cluster could not assign a node ID to the restarting node. (Bug#25741)
- **Disk Data:** Changing a column specification or issuing a `TRUNCATE` statement on a Disk Data table caused the table to become an in-memory table.

This fix supersedes an incomplete fix that was made for this issue in MySQL 5.1.15. (Bug#24667, Bug#25296)

- **Cluster Replication:** It was possible for API nodes to begin interacting with the cluster subscription manager before they were fully connected to the cluster. (Bug#27728)
- **Cluster Replication:** Under very high loads, checkpoints could be read or written with checkpoint indexes out of order.

[Bug#27651](#))

- **Cluster API:** An issue with the way in which the `NdbDictionary::Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. ([Bug#27663](#))
- An `INSERT` followed by a delete `DELETE` on the same `NDB` table caused a memory leak. ([Bug#27756](#))

This regression was introduced by [Bug#20612](#)

- `mysqldump` could not dump log tables. ([Bug#26121](#))
- The `--with-readline` option for `configure` did not work for commercial source packages, but no error message was printed to that effect. Now a message is printed. ([Bug#25530](#))

### 19.17.3.18. Changes in MySQL Cluster NDB 6.1.6 (5.1.15-ndb-6.1.6) (Not released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server in order for the table to be re-created with the new schema.

See [Section 19.11.4, “Cluster Replication Schema and Tables”](#), for additional information.

Bugs fixed:

- **MySQL Cluster:** A data node failing while another data node was restarting could leave the cluster in an inconsistent state. In certain rare cases, this could lead to a race condition and the eventual forced shutdown of the cluster. ([Bug#27466](#))
- **MySQL Cluster:** It was not possible to set `LockPagesInMainMemory` equal to 0. ([Bug#27291](#))
- **MySQL Cluster:** A race condition could sometimes occur if the node acting as master failed while node IDs were still being allocated during startup. ([Bug#27286](#))
- **MySQL Cluster:** When a data node was taking over as the master node, a race condition could sometimes occur as the node was assuming responsibility for handling of global checkpoints. ([Bug#27283](#))
- **MySQL Cluster:** `mysqld` could crash shortly after a data node failure following certain DML operations. ([Bug#27169](#))
- **MySQL Cluster:** The same failed request from an API node could be handled by the cluster multiple times, resulting in reduced performance. ([Bug#27087](#))
- **MySQL Cluster:** The failure of a data node while restarting could cause other data nodes to hang or crash. ([Bug#27003](#))
- **MySQL Cluster:** `mysqld` processes would sometimes crash under high load.

#### Note

This fix improves on and replaces a fix for this bug that was made in MySQL Cluster NDB 6.1.5.

([Bug#26825](#))

- **Disk Data:** `DROP INDEX` on a Disk Data table did not always move data from memory into the tablespace. (Bug#25877)
- **Cluster Replication:** Trying to replicate a large number of frequent updates with a relatively small relay log (`max-relay-log-size` set to 1M or less) could cause the slave to crash. (Bug#27529)
- **Cluster API:** An issue with the way in which the `NdbDictionary::Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. (Bug#27663)
- **Cluster API:** A delete operation using a scan followed by an insert using a scan could cause a data node to fail. (Bug#27203)

### 19.17.3.19. Changes in MySQL Cluster NDB 6.1.5 (5.1.15-ndb-6.1.5) (15 March 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Section C.1.13, “Changes in MySQL 5.1.15 (25 January 2007)”).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server in order for the table to be re-created with the new schema.

See Section 19.11.4, “Cluster Replication Schema and Tables”, for additional information.

Bugs fixed:

- **MySQL Cluster:** Creating a table on one SQL node while in single user mode caused other SQL nodes to crash. (Bug#26997)
- **MySQL Cluster:** `mysqld` processes would sometimes crash under high load.

#### Note

This fix was reverted in MySQL Cluster NDB 6.1.6.

(Bug#26825)

- **MySQL Cluster:** An infinite loop in an internal logging function could cause trace logs to fill up with `UNKNOWN SIGNAL TYPE` error messages and thus grow to unreasonable sizes. (Bug#26720)
- **Disk Data:** When creating a log file group, setting `INITIAL_SIZE` to less than `UNDO_BUFFER_SIZE` caused data nodes to crash. (Bug#25743)

### 19.17.3.20. Changes in MySQL Cluster NDB 6.1.4 (5.1.15-ndb-6.1.4) (09 March 2007))

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Section C.1.13, “Changes in MySQL 5.1.15 (25 January 2007)”).

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** An `--ndb-wait-connected` option has been added for `mysqld`. It causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections. See [here](#), for more information.
- **Cluster API:** It is now possible to specify the transaction coordinator when starting a transaction. See `Ndb::startTransaction()`, for more information.
- **Cluster API:** It is now possible to iterate over all existing `Ndb` objects using three new methods of the `Ndb_cluster_connection` class:
  - `lock_ndb_objects()`
  - `get_next_ndb_object()`
  - `unlock_ndb_objects()`
 For more information about these methods and their use, see `ndb_cluster_connection::get_next_ndb_object()`, in the MySQL Cluster API Guide.
- Data node memory allocation has been improved. On 32-bit platforms, it should now be possible to use close to 3GB RAM for `IndexMemory` and `DataMemory` combined.

Bugs fixed:

- **MySQL Cluster:** Using only the `--print_data` option (and no other options) with `ndb_restore` caused `ndb_restore` to fail. ([Bug#26741](#))  
This regression was introduced by [Bug#14612](#)
- **MySQL Cluster:** An inadvertent use of unaligned data caused `ndb_restore` to fail on some 64-bit platforms, including Sparc and Itanium-2. ([Bug#26739](#))
- Assigning a node ID greater than 63 to an SQL node caused an out of bounds error in `mysqld`. It should now be possible to assign to SQL nodes node IDs up to 255. ([Bug#26663](#))

### 19.17.3.21. Changes in MySQL Cluster NDB 6.1.3 (5.1.15-ndb-6.1.3) (25 February 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** The `ndbd_redo_log_reader` utility is now part of the default build. For more information, see [Section 19.10.11, “ndbd\\_redo\\_log\\_reader — Check and Print Content of Cluster Redo Log”](#).
- **Cluster API:** A new `listEvents()` method has been added to the `Dictionary` class. See `Dictionary::listEvents()`, for more information.
- The `ndb_show_tables` utility now displays information about table events. See [Section 19.10.14, “ndb\\_show\\_tables](#)

— [Display List of NDB Tables](#)”, for more information.

- It is now possible to disable arbitration by setting `ArbitrationRank=0` on all management and SQL nodes.

Bugs fixed:

- **MySQL Cluster:** An invalid pointer was returned following a `FSCLOSECONF` signal when accessing the REDO logs during a node restart or system restart. ([Bug#26515](#))
- **MySQL Cluster:** The `InvalidUndoBufferSize` error used the same error code (763) as the `IncompatibleVersions` error. `InvalidUndoBufferSize` now uses its own error code (779). ([Bug#26490](#))
- **MySQL Cluster:** The failure of a data node when restarting it with `--initial` could lead to failures of subsequent data node restarts. ([Bug#26481](#))
- **MySQL Cluster:** Takeover for local checkpointing due to multiple failures of master nodes was sometimes incorrectly handled. ([Bug#26457](#))
- **MySQL Cluster:** The `LockPagesInMainMemory` parameter was not read until after distributed communication had already started between cluster nodes. When the value of this parameter was 1, this could sometimes result in data node failure due to missed heartbeats. ([Bug#26454](#))
- **MySQL Cluster:** Under some circumstances, following the restart of a management node, all data nodes would connect to it normally, but some of them subsequently failed to log any events to the management node. ([Bug#26293](#))
- **MySQL Cluster:** No appropriate error message was provided when there was insufficient REDO log file space for the cluster to start. ([Bug#25801](#))
- **MySQL Cluster:** A memory allocation failure in `SUMA` (the cluster Subscription Manager) could cause the cluster to crash. ([Bug#25239](#))
- **MySQL Cluster:** The message `ERROR 0 IN READAUTOINCREMENTVALUE(): NO ERROR` was written to the error log whenever `SHOW TABLE STATUS` was performed on a Cluster table that did not have an `AUTO_INCREMENT` column.

#### Note

This improves on and supersedes an earlier fix that was made for this issue in MySQL 5.1.12.

([Bug#21033](#))

- **Disk Data:** A memory overflow could occur with tables having a large amount of data stored on disk, or with queries using a very high degree of parallelism on Disk Data tables. ([Bug#26514](#))
- **Disk Data:** Use of a tablespace whose `INITIAL_SIZE` was greater than 1 GB could cause the cluster to crash. ([Bug#26487](#))

### 19.17.3.22. Changes in MySQL Cluster NDB 6.1.2 (5.1.15-ndb-6.1.2) (07 February 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **MySQL Cluster:** Using node IDs greater than 48 could sometimes lead to incorrect memory access and a subsequent forced shutdown of the cluster. ([Bug#26267](#))

### 19.17.3.23. Changes in MySQL Cluster NDB 6.1.1 (5.1.15-ndb-6.1.1) (01 February 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.1 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.13, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** A single cluster can now support up to 255 API nodes, including MySQL servers acting as SQL nodes. See [Section 19.14.8, “Issues Exclusive to MySQL Cluster”](#), for more information.

Bugs fixed:

- **Cluster API: Disk Data:** A delete and a read performed in the same operation could cause one or more data nodes to crash. This could occur when the operation affected more than 5 columns concurrently, or when one or more of the columns was of the `VARCHAR` type and was stored on disk. ([Bug#25794](#))
- A memory leak could cause problems during a node or cluster shutdown or failure. ([Bug#25997](#))
- An element could sometimes be inserted twice into the hash table, causing a data node to crash. ([Bug#25286](#))

### 19.17.3.24. Changes in MySQL Cluster NDB 6.1.0 (5.1.14-ndb-6.1.0) (20 December 2006)

This is the first MySQL Cluster NDB 6.1 release, incorporating new features and bugfixes made for the `NDBCLUSTER` storage engine made since branching from MySQL 5.1.14 standard (see [Section C.1.14, “Changes in MySQL 5.1.14 \(05 December 2006\)”](#)).

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **MySQL Cluster:** A new configuration parameter `MemReportFrequency` allows for additional control of data node memory usage. Previously, only warnings at predetermined percentages of memory allocation were given; setting this parameter allows for that behavior to be overridden. For more information, see [Section 19.3.4.5, “Defining Data Nodes”](#).

Bugs fixed:

- **MySQL Cluster:** When a data node was shut down using the management client `STOP` command, a connection event (`NDB_LE_Connected`) was logged instead of a disconnection event (`NDB_LE_Disconnected`). ([Bug#22773](#))
- **MySQL Cluster:** `SELECT` statements with a `BLOB` or `TEXT` column in the selected column list and a `WHERE` condition including a primary key lookup on a `VARCHAR` primary key produced empty result sets. ([Bug#19956](#))
- **Disk Data:** `MEDIUMTEXT` columns of Disk Data tables were stored in memory rather than on disk, even if the columns were not indexed. ([Bug#25001](#))
- **Disk Data:** Performing a node restart with a newly dropped Disk Data table could lead to failure of the node during the restart.

([Bug#24917](#))

- **Disk Data:** When restoring from backup a cluster containing any Disk Data tables with hidden primary keys, a node failure resulted which could lead to a crash of the cluster. ([Bug#24166](#))
- **Disk Data:** Repeated `CREATE`, `DROP`, or `TRUNCATE` in various combinations with system restarts between these operations could lead to the eventual failure of a system restart. ([Bug#21948](#))
- **Disk Data:** Extents that should have been available for re-use following a `DROP TABLE` operation were not actually made available again until after the cluster had performed a local checkpoint. ([Bug#17605](#))
- **Cluster API:** Invoking the `NdbTransaction::execute()` method using execution type `Commit` and abort option `AO_IgnoreError` could lead to a crash of the transaction coordinator (DBTC). ([Bug#25090](#))
- **Cluster API:** A unique index lookup on a non-existent tuple could lead to a data node timeout (error 4012). ([Bug#25059](#))
- **Cluster API:** When using the `NdbTransaction::execute()` method, a very long timeout (greater than 5 minutes) could result if the last data node being polled was disconnected from the cluster. ([Bug#24949](#))
- **Cluster API:** Due to an error in the computation of table fragment arrays, some transactions were not executed from the correct starting point. ([Bug#24914](#))
- Under certain rare circumstances, local checkpoints were not performed properly, leading to an inability to restart one or more data nodes. ([Bug#24664](#))

---

# Chapter 20. Partitioning

This chapter discusses *user-defined partitioning*, as implemented in MySQL 5.1.

An introduction to partitioning and partitioning concepts may be found in [Section 20.1, “Overview of Partitioning in MySQL”](#).

MySQL supports several types of partitioning, which are discussed in [Section 20.2, “Partition Types”](#), as well as subpartitioning, which is described in [Section 20.2.5, “Subpartitioning”](#).

Methods of adding, removing, and altering partitions in existing partitioned tables are covered in [Section 20.3, “Partition Management”](#).

Table maintenance commands for use with partitioned tables are discussed in [Section 20.3.3, “Maintenance of Partitions”](#).

Beginning with MySQL 5.1.6, the `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See [Section 26.19, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#), for more information; for some examples of queries against this table, see [Section 20.2.6, “How MySQL Partitioning Handles NULL Values”](#).

## Important

Partitioned tables created with MySQL versions prior to 5.1.6 cannot be read by a 5.1.6 or later MySQL Server. In addition, the `INFORMATION_SCHEMA.TABLES` table cannot be used if such tables are present on a 5.1.6 server. Beginning with MySQL 5.1.7, a suitable warning message is generated instead, to alert the user that incompatible partitioned tables have been found by the server.

If you are using partitioned tables which were created in MySQL 5.1.5 or earlier, be sure to see [Section C.1.22, “Changes in MySQL 5.1.6 \(01 February 2006\)”](#) for more information and suggested workarounds *before* upgrading to MySQL 5.1.6 or later.

The partitioning implementation in MySQL 5.1 is still undergoing development. For known issues with MySQL partitioning, see [Section 20.5, “Restrictions and Limitations on Partitioning”](#), where we have noted these.

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.** Other sources of information about user-defined partitioning in MySQL include the following:

- [MySQL Partitioning Forum](#)

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström's Blog](#)

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- [PlanetMySQL](#)

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.1 binaries are available from <http://dev.mysql.com/downloads/mysql/5.1.html>. However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our Bazaar repository. To enable partitioning, you need to compile the server using the `--with-partition` option. For more information about building MySQL, see [Section 2.9, “MySQL Installation Using a Source Distribution”](#). If you have problems compiling a partitioning-enabled MySQL 5.1 build, check the [MySQL Partitioning Forum](#) and ask for assistance there if you do not find a solution to your problem already posted.

## 20.1. Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.1.

For information on partitioning restrictions and feature limitations, see [Section 20.5, “Restrictions and Limitations on Partitioning”](#).

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with

which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the filesystem, hardware or even both. In MySQL, the [InnoDB](#) storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see [Section 7.6.1, “Using Symbolic Links”](#), for an explanation of how this is done).

*Partitioning* takes this notion a step further, by allowing you to distribute portions of individual tables across a filesystem according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be either an integer column value, or a function acting on one or more column values and returning an integer. The value of this expression is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be non-constant and non-random. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either `NULL` or an integer *intval* such that

```
-MAXVALUE <= intval <= MAXVALUE
```

(`MAXVALUE` is used to represent the least upper bound for the type of integer in question. `-MAXVALUE` represents the greatest lower bound.) There are some additional restrictions on partitioning functions; see [Section 20.5, “Restrictions and Limitations on Partitioning”](#), for more information about these.

Examples of partitioning functions can be found in the discussions of partitioning types later in this chapter (see [Section 20.2, “Partition Types”](#)), as well as in the partitioning syntax descriptions given in [Section 12.1.10, “CREATE TABLE Syntax”](#).

This is known as *horizontal partitioning* — that is, different rows of a table may be assigned to different physical partitions. MySQL 5.1 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are not at this time any plans to introduce vertical partitioning into MySQL 5.1.

Partitioning support is included in all binary releases of MySQL 5.1. If you are compiling MySQL 5.1 from source, the build must be configured using `--with-partition` to enable partitioning.

If the MySQL binary is built with partitioning support, nothing further needs to be done in order to enable it (for example, no special entries are required in your `my.cnf` file). You can determine whether your MySQL server supports partitioning by means of a `SHOW VARIABLES` command such as this one:

```
mysql> SHOW VARIABLES LIKE '%partition%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_partitioning | YES |
+-----+-----+
1 row in set (0.00 sec)
```

If you do not see the `have_partitioning` variable with the value `YES` listed as shown above in the output of an appropriate `SHOW VARIABLES`, then your version of MySQL does not support partitioning.

### Note

Prior to MySQL 5.1.6, this variable was named `have_partition_engine`. ([Bug#16718](#))

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.1, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use [MyISAM](#) for one partition and [InnoDB](#) for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

### Note

MySQL partitioning cannot be used with the [MERGE](#) or [CSV](#) storage engines. Beginning with MySQL 5.1.15, [FEDERATED](#) tables also cannot be partitioned ([Bug#22451](#)). Prior to MySQL 5.1.6, it was also not feasible to create a partitioned table using the [BLACKHOLE](#) storage engine ([Bug#14524](#)). Partitioning by `KEY` is possible with [NDB-CLUSTER](#), but other types of user-defined partitioning are not supported for tables using this storage engine.

To employ a particular storage engine for a partitioned table, it is necessary only to use the `[STORAGE] ENGINE` option just as you would for a non-partitioned table. However, you should keep in mind that `[STORAGE] ENGINE` (and other table options) need to be listed *before* any partitioning options are used in a `CREATE TABLE` statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the [InnoDB](#) storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
ENGINE=INNODB
```

```
PARTITION BY HASH(MONTH(tr_date))
PARTITIONS 6;
```

**Note**

Each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 5.1 this has no effect.

**Important**

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or *vice versa*, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

**Note**

Prior to MySQL 5.1.18, these options were permitted even when the `NO_DIR_IN_CREATE` server SQL mode was in effect. (Bug#24633)

The `DATA DIRECTORY` and `INDEX DIRECTORY` options have no effect when defining partitions for tables using the InnoDB storage engine.

`DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions on Windows. Beginning with MySQL 5.1.24, these options are ignored on Windows, except that a warning is generated. (Bug#30459)

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See Section 20.3, “Partition Management”, for more information on these options.

Some of the advantages of partitioning include:

- Being able to store more data in one table than can be held on a single disk or filesystem partition.
- Data that loses its usefulness can often be easily removed from the table by dropping the partition containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding a new partition specifically for that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, thereby excluding any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been so when the partitioning scheme was first set up. This capability, sometimes referred to as *partition pruning*, was implemented in MySQL 5.1.6. For more information, see Section 20.4, “Partition Pruning”.

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as `SUM()` and `COUNT()` can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;` By “parallelized,” we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.
- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as Partitioning development continues.

## 20.2. Partition Types

This section discusses the types of partitioning which are available in MySQL 5.1. These include:

- **RANGE partitioning:** Assigns rows to partitions based on column values falling within a given range. See Section 20.2.1, “RANGE Partitioning”.
- **LIST partitioning:** Similar to partitioning by range, except that the partition is selected based on columns matching one of a set of discrete values. See Section 20.2.2, “LIST Partitioning”.

- **HASH partitioning:** A partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a non-negative integer value. See [Section 20.2.3, “HASH Partitioning”](#).
- **KEY partitioning:** Similar to partitioning by hash, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. See [Section 20.2.4, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.1. However, it is not difficult in MySQL to create partitioning schemes based on [DATE](#), [TIME](#), or [DATETIME](#) columns, or based on expressions making use of such columns.

When partitioning by [KEY](#) or [LINEAR KEY](#), you can use a [DATE](#), [TIME](#), or [DATETIME](#) column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
 firstname VARCHAR(25) NOT NULL,
 lastname VARCHAR(25) NOT NULL,
 username VARCHAR(16) NOT NULL,
 email VARCHAR(35),
 joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or [NULL](#). If you wish to use date-based partitioning by [RANGE](#), [LIST](#), [HASH](#), or [LINEAR HASH](#), you can simply employ a function that operates on a [DATE](#), [TIME](#), or [DATETIME](#) column and returns such a value, as shown here:

```
CREATE TABLE members (
 firstname VARCHAR(25) NOT NULL,
 lastname VARCHAR(25) NOT NULL,
 username VARCHAR(16) NOT NULL,
 email VARCHAR(35),
 joined DATE NOT NULL
)
PARTITION BY RANGE(YEAR(joined)) (
 PARTITION p0 VALUES LESS THAN (1960),
 PARTITION p1 VALUES LESS THAN (1970),
 PARTITION p2 VALUES LESS THAN (1980),
 PARTITION p3 VALUES LESS THAN (1990),
 PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found here:

- [Section 20.2.1, “RANGE Partitioning”](#)
- [Section 20.2.3, “HASH Partitioning”](#)
- [Section 20.2.3.1, “LINEAR HASH Partitioning”](#)

For more complex examples of date-based partitioning, see:

- [Section 20.4, “Partition Pruning”](#)
- [Section 20.2.5, “Subpartitioning”](#)

MySQL partitioning is optimized for use with the [TO\\_DAYS\(\)](#) and [YEAR\(\)](#) functions. However, you can use other date and time functions that return an integer or [NULL](#), such as [WEEKDAY\(\)](#), [DAYOFYEAR\(\)](#), or [MONTH\(\)](#). See [Section 11.6, “Date and Time Functions”](#), for more information about such functions.

It is important to remember — regardless of the type of partitioning that you use — that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the [RANGE](#) and [LIST](#) partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For [HASH](#) partitioning, the user function employed must return an integer value greater than 0. For [KEY](#) partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However,

you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)(
-> PARTITION mypart VALUES IN (1,3,5),
-> PARTITION MyPart VALUES IN (2,4,6)
->);
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, non-zero integer literal with no leading zeroes, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. (Beginning with MySQL 5.1.12, decimal fractions are no longer truncated, but instead are disallowed entirely.)

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in [Section 12.1.10, “CREATE TABLE Syntax”](#).

## 20.2.1. RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
);
```

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
 PARTITION p0 VALUES LESS THAN (6),
 PARTITION p1 VALUES LESS THAN (11),
 PARTITION p2 VALUES LESS THAN (16),
 PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a `switch ... case` in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Michael', 'Widenius', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21<sup>st</sup> store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than highest value explicitly named:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
 PARTITION p0 VALUES LESS THAN (6),
 PARTITION p1 VALUES LESS THAN (11),
 PARTITION p2 VALUES LESS THAN (16),
 PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

**Note**

Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see [Section 20.2.2, “LIST Partitioning”](#). Also see [Section 12.2.4, “INSERT Syntax”](#), for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future — when the number of stores has increased to 25, 30, or more — you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 20.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes — that is, based on ranges of `job_code` column values. For example — assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions — you could create the partitioned table using the following:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
 PARTITION p0 VALUES LESS THAN (100),
 PARTITION p1 VALUES LESS THAN (1000),
 PARTITION p2 VALUES LESS THAN (10000)
);
```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN (<)` comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY RANGE (YEAR(separated)) (
 PARTITION p0 VALUES LESS THAN (1991),
 PARTITION p1 VALUES LESS THAN (1996),
 PARTITION p2 VALUES LESS THAN (2001),
 PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

Range partitioning is particularly useful when:

- You want or need to delete “old” data. If you are using the partitioning scheme shown immediately above, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 12.1.4, “ALTER TABLE Syntax”](#), and [Section 20.3, “Partition Management”](#), for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `SELECT COUNT(*) FROM employees WHERE YEAR(separated) = 2000 GROUP BY`

`store_id`; MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 20.4, “Partition Pruning”](#), for more information about how this is accomplished.

## 20.2.2. LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by [RANGE](#), each partition must be explicitly defined. The chief difference is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where *expr* is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where *value\_list* is a comma-separated list of integers.

### Note

In MySQL 5.1, it is possible to match against only a list of integers (and possibly `NULL` — see [Section 20.2.6, “How MySQL Partitioning Handles NULL Values”](#)) when partitioning by `LIST`.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see [Section 12.1.10, “CREATE TABLE Syntax”](#).

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
);
```

(This is the same table used as a basis for the examples in [Section 20.2.1, “RANGE Partitioning”](#).)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table:

| Region  | Store ID Numbers     |
|---------|----------------------|
| North   | 3, 5, 6, 9, 17       |
| East    | 1, 2, 10, 11, 19, 20 |
| West    | 4, 12, 13, 14, 18    |
| Central | 7, 8, 15, 16         |

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY LIST(store_id) (
 PARTITION pNorth VALUES IN (3,5,6,9,17),
 PARTITION pEast VALUES IN (1,2,10,11,19,20),
 PARTITION pWest VALUES IN (4,12,13,14,18),
 PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. All rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees DROP PARTITION pWest`; which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18)`;

As with [RANGE](#) partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 20.2.5, “Subpartitioning”](#).

Unlike the case with [RANGE](#) partitioning, there is no “catch-all” such as [MAXVALUE](#); all expected values for the partitioning expression should be covered in [PARTITION ... VALUES IN \(...\)](#) clauses. An [INSERT](#) statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
-> c1 INT,
-> c2 INT
->)
-> PARTITION BY LIST(c1) (
-> PARTITION p0 VALUES IN (1, 4, 7),
-> PARTITION p1 VALUES IN (2, 5, 8)
->);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): TABLE HAS NO PARTITION FOR VALUE 3
```

When inserting multiple rows using a single [INSERT](#) statement, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not:

```
mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT INTO h2 VALUES (4, 7), (3, 5), (6, 0);
ERROR 1525 (HY000): TABLE HAS NO PARTITION FOR VALUE 3
mysql> SELECT * FROM h2;
+-----+-----+
| c1 | c2 |
+-----+-----+
| 4 | 7 |
+-----+-----+
1 row in set (0.00 sec)
```

You can cause this type of error to be ignored by using the [IGNORE](#) key word. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values *are* inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5 Duplicates: 2 Warnings: 0

mysql> SELECT * FROM h2;
+-----+-----+
| c1 | c2 |
+-----+-----+
7	5
1	9
2	5
+-----+-----+
3 rows in set (0.00 sec)
```

### 20.2.3. HASH Partitioning

Partitioning by [HASH](#) is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using [HASH](#) partitioning, it is necessary to append to the [CREATE TABLE](#) statement a [PARTITION BY HASH \(expr\)](#) clause, where *expr* is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you will most likely want to follow this with a [PARTITIONS num](#) clause, where *num* is a non-negative integer representing the number of partitions into which the table is to be divided.

For example, the following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a [PARTITIONS](#) clause, the number of partitions defaults to 1.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for *expr*. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY HASH(YEAR(hired))
PARTITIONS 4;
```

You may use any function or other expression for *expr* that is valid in MySQL, so long as it returns a non-constant, non-random integer value. (In other words, it should be varying but deterministic.) However, you should keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where *date\_col* is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of *date\_col*, because for every change in the value of *date\_col*, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to *date\_col* is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in *date\_col* produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of *date\_col* and there is no possible change in *date\_col* that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named *int\_col* whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of *int\_col* is not guaranteed to produce a proportional change in the value of the expression. Changing the value of *int\_col* by a given amount can produce by widely different changes in the value of the expression. For example, changing *int\_col* from 5 to 6 produces a change of `-1` in the value of the expression, but changing the value of *int\_col* from 6 to 7 produces a change of `-7` in the expression value.

In other words, the more closely the graph of the column value *versus* the value of the expression follows a straight line as traced by the equation  $y=nx$  where *n* is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of *num* partitions to use based on the modulus of the result of the user function. In other words, for an expression *expr*, the partition in which the record is stored is partition number *N*, where  $N = \text{MOD}(\text{expr}, \text{num})$ . For example, suppose table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH(YEAR(col3))
PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
= MOD(2005,4)
= 1
```

MySQL 5.1 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 20.2.3.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also — depending on the circumstances — be evaluated when records are deleted.

## ■ Note

If a table to be partitioned has a **UNIQUE** key, then any columns supplied as arguments to the **HASH** user function or to the **KEY**'s *column\_list* must be part of that key.

### 20.2.3.1. LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the **LINEAR** keyword in the **PARTITION BY** clause, as shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY LINEAR HASH(YEAR(hired))
PARTITIONS 4;
```

Given an expression *expr*, the partition in which the record is stored when linear hashing is used is partition number *N* from among *num* partitions, where *N* is derived according to the following algorithm:

1. Find the next power of 2 greater than *num*. We call this value *V*; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(For example, suppose that *num* is 13. Then **LOG(2, 13)** is 3.7004397181411. **CEILING(3.7004397181411)** is 4, and **V = POWER(2, 4)**, which is 16.)

2. Set  $N = F(\textit{column\_list}) \& (V - 1)$ .
3. While  $N \geq \textit{num}$ :
  - Set  $V = \text{CEIL}(V / 2)$
  - Set  $N = N \& (V - 1)$

For example, suppose that the table **t1**, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH(YEAR(col3))
PARTITIONS 6;
```

Now assume that you want to insert two records into **t1** having the **col3** column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING(LOG(2,6))) = 8
N = YEAR('2003-04-14') & (8 - 1)
 = 2003 & 7
 = 3
(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
 = 1998 & 7
 = 6
(6 >= 6 is TRUE: additional step required)
N = 6 & CEILING(8 / 2)
 = 6 & 3
 = 2
(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

## 20.2.4. KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASS-WORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are that:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of one or more column names. Beginning with MySQL 5.1.5, the column or columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one.

Beginning with MySQL 5.1.6, `KEY` takes a list of zero or more column names. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.1.6 or later:

```
CREATE TABLE k1 (
 id INT NOT NULL PRIMARY KEY,
 name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
 id INT NOT NULL,
 name VARCHAR(20),
 UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tm1 (
 s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified.

### Note

In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.

For additional information about this issue, see [Section 20.5, “Restrictions and Limitations on Partitioning”](#).

### Note

Also beginning with MySQL 5.1.6, tables using the `NDBCLUSTER` storage engine are implicitly partitioned by `KEY`, again using the table's primary key as the partitioning key. In the event that the Cluster table has no explicit primary key, the “hidden” primary key generated by the `NDB` storage engine for each Cluster table is used as the partitioning key.

### Important

For a key-partitioned table using any MySQL storage engine other than `NDBCLUSTER`, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): FIELD IN LIST OF FIELDS FOR PARTITION FUNCTION NOT FOUND IN TABLE`. This is not an issue for MySQL Cluster tables which are partitioned by `KEY`; in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See [Chapter 19, MySQL Cluster](#).

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
 col1 INT NOT NULL,
 col2 CHAR(5),
 col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using [LINEAR](#) has the same effect on [KEY](#) partitioning as it does on [HASH](#) partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 20.2.3.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

## 20.2.5. Subpartitioning

Subpartitioning — also known as *composite partitioning* — is the further division of each partition in a partitioned table. For example, consider the following [CREATE TABLE](#) statement:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased))
SUBPARTITIONS 2 (
 PARTITION p0 VALUES LESS THAN (1990),
 PARTITION p1 VALUES LESS THAN (2000),
 PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

Table `ts` has 3 [RANGE](#) partitions. Each of these partitions — `p0`, `p1`, and `p2` — is further divided into 2 subpartitions. In effect, the entire table is divided into  $3 * 2 = 6$  partitions. However, due to the action of the [PARTITION BY RANGE](#) clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

In MySQL 5.1, it is possible to subpartition tables that are partitioned by [RANGE](#) or [LIST](#). Subpartitions may use either [HASH](#) or [KEY](#) partitioning. This is also known as *composite partitioning*.

It is also possible to define subpartitions explicitly using [SUBPARTITION](#) clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0,
 SUBPARTITION s1
),
 PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s2,
 SUBPARTITION s3
),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s4,
 SUBPARTITION s5
)
);
```

Some syntactical items of note:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using [SUBPARTITION](#) on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0,
 SUBPARTITION s1
),
 PARTITION p1 VALUES LESS THAN (2000),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s2,
 SUBPARTITION s3
)
);
```

This statement would still fail even if it included a [SUBPARTITIONS 2](#) clause.

- Each **SUBPARTITION** clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.
- In MySQL 5.1.7 and earlier, names of subpartitions were required to be unique within each partition, but did not have to be unique within the table as a whole. Beginning with MySQL 5.1.8, subpartition names must be unique across the entire table. For example, the following **CREATE TABLE** statement is valid in MySQL 5.1.8 and later:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0,
 SUBPARTITION s1
),
 PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s2,
 SUBPARTITION s3
),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s4,
 SUBPARTITION s5
)
);
```

(The previous statement is also valid for versions of MySQL prior to 5.1.8.)

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0
 DATA DIRECTORY = '/disk0/data'
 INDEX DIRECTORY = '/disk0/idx',
 SUBPARTITION s1
 DATA DIRECTORY = '/disk1/data'
 INDEX DIRECTORY = '/disk1/idx'
),
 PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s2
 DATA DIRECTORY = '/disk2/data'
 INDEX DIRECTORY = '/disk2/idx',
 SUBPARTITION s3
 DATA DIRECTORY = '/disk3/data'
 INDEX DIRECTORY = '/disk3/idx'
),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s4
 DATA DIRECTORY = '/disk4/data'
 INDEX DIRECTORY = '/disk4/idx',
 SUBPARTITION s5
 DATA DIRECTORY = '/disk5/data'
 INDEX DIRECTORY = '/disk5/idx'
)
);
```

In this case, a separate disk is used for the data and for the indexes of each **RANGE**. Many other variations are possible; another example might be:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0a
 DATA DIRECTORY = '/disk0'
 INDEX DIRECTORY = '/disk1',
 SUBPARTITION s0b
 DATA DIRECTORY = '/disk2'
 INDEX DIRECTORY = '/disk3'
),
 PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s1a
 DATA DIRECTORY = '/disk4/data'
 INDEX DIRECTORY = '/disk4/idx',
 SUBPARTITION s1b
 DATA DIRECTORY = '/disk5/data'
 INDEX DIRECTORY = '/disk5/idx'
),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s2a,
 SUBPARTITION s2b
)
);
```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:
  - The data for subpartition `s0a` is stored on `/disk0`.
  - The indexes for subpartition `s0a` are stored on `/disk1`.
  - The data for subpartition `s0b` is stored on `/disk2`.
  - The indexes for subpartition `s0b` are stored on `/disk3`.
- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:
  - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4` — the data in `/disk4/data`, and the indexes in `/disk4/idx`.
  - Data and indexes belonging to `p1`'s second subpartition (`s1b`) are stored on `/disk5` — the data in `/disk5/data`, and the indexes in `/disk5/idx`.
- Rows reflecting dates from the year 2000 to the present (partition `p2`) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See [Section 20.3, “Partition Management”](#), for an explanation of how this can be done.

Beginning with MySQL 5.1.18, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are disallowed when the `NO_DIR_IN_CREATE` server SQL mode is in effect. This is true for partitions and subpartitions.

## 20.2.6. How MySQL Partitioning Handles `NULL` Values

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. Beginning with MySQL 5.1.8, the partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

**Handling of `NULL` with `RANGE` partitioning.** If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. For example, consider these two tables in a database named `p`, created as follows:

```
mysql> CREATE TABLE t1 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY RANGE(c1) (
-> PARTITION p0 VALUES LESS THAN (0),
-> PARTITION p1 VALUES LESS THAN (10),
-> PARTITION p2 VALUES LESS THAN MAXVALUE
->);
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY RANGE(c1) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (10),
-> PARTITION p3 VALUES LESS THAN MAXVALUE
->);
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
```

```

+-----+-----+-----+-----+-----+
t1	p0	0	0	0
t1	p1	0	0	0
t1	p2	0	0	0
t2	p0	0	0	0
t2	p1	0	0	0
t2	p2	0	0	0
t2	p3	0	0	0
+-----+-----+-----+-----+-----+
7 rows in set (0.00 sec)

```

(For more information about this table, see [Section 26.19](#), “The `INFORMATION_SCHEMA PARTITIONS` Table”.) Now let us populate each of these tables with a single row containing a `NULL` in the column used as the partitioning key, and verify that the rows were inserted using a pair of `SELECT` statements:

```

mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+-----+-----+
| id | name |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+-----+
| id | name |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)

```

You can see which partitions are used to store the inserted rows by rerunning the previous query against `INFORMATION_SCHEMA.PARTITIONS` and inspecting the output:

```

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1 | p0 | 1 | 20 | 20 |
| t1 | p1 | 0 | 0 | 0 |
| t1 | p2 | 0 | 0 | 0 |
| t2 | p0 | 1 | 20 | 20 |
| t2 | p1 | 0 | 0 | 0 |
| t2 | p2 | 0 | 0 | 0 |
| t2 | p3 | 0 | 0 | 0 |
+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)

```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then rerunning the `SELECT` statements:

```

mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)

```

(For more information on `ALTER TABLE ... DROP PARTITION`, see [Section 12.1.4](#), “`ALTER TABLE Syntax`”.)

## Important

Prior to MySQL 5.1.8, `RANGE` partitioning treated a partitioning expression value of `NULL` as 0 with respect to determining placement. (The only way to circumvent this behavior was to design tables so as not to allow nulls, usually by declaring columns `NOT NULL`.) If you have a `RANGE` partitioning scheme that depends on this earlier behavior, you will need to re-implement it when upgrading to MySQL 5.1.8 or later. ([Bug#15447](#))

`NULL` is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```

CREATE TABLE tndate (
 id INT,
 dt DATE
)
PARTITION BY RANGE(YEAR(dt)) (
 PARTITION p0 VALUES LESS THAN (1990),

```

```

PARTITION p1 VALUES LESS THAN (2000),
PARTITION p2 VALUES LESS THAN MAXVALUE
);

```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

**Handling of `NULL` with `LIST` partitioning.** A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```

mysql> CREATE TABLE ts1 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY LIST(c1) (
-> PARTITION p0 VALUES IN (0, 3, 6),
-> PARTITION p1 VALUES IN (1, 4, 7),
-> PARTITION p2 VALUES IN (2, 5, 8)
->);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): TABLE HAS NO PARTITION FOR VALUE 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): TABLE HAS NO PARTITION FOR VALUE NULL

```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```

mysql> CREATE TABLE ts2 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY LIST(c1) (
-> PARTITION p0 VALUES IN (0, 3, 6),
-> PARTITION p1 VALUES IN (1, 4, 7),
-> PARTITION p2 VALUES IN (2, 5, 8),
-> PARTITION p3 VALUES IN (NULL)
->);
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY LIST(c1) (
-> PARTITION p0 VALUES IN (0, 3, 6),
-> PARTITION p1 VALUES IN (1, 4, 7, NULL),
-> PARTITION p2 VALUES IN (2, 5, 8)
->);
Query OK, 0 rows affected (0.01 sec)

```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```

mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';

```

| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
|------------|----------------|------------|----------------|-------------|
| ts2        | p0             | 0          | 0              | 0           |
| ts2        | p1             | 0          | 0              | 0           |
| ts2        | p2             | 0          | 0              | 0           |
| ts2        | p3             | 1          | 20             | 20          |
| ts3        | p0             | 0          | 0              | 0           |
| ts3        | p1             | 1          | 20             | 20          |
| ts3        | p2             | 0          | 0              | 0           |

```

7 rows in set (0.01 sec)

```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

**Handling of `NULL` with `HASH` and `KEY` partitioning.** `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify

this behavior by examining the effects on the filesystem of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```
mysql> CREATE TABLE th (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY HASH(c1)
-> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```

The partitions belonging to this table can be viewed like this:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
|------------|----------------|------------|----------------|-------------|
| th         | p0             | 0          | 0              | 0           |
| th         | p1             | 0          | 0              | 0           |

2 rows in set (0.00 sec)

Note that `TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
```

| c1   | c2     |
|------|--------|
| NULL | mothra |
| 0    | gigan  |

2 rows in set (0.01 sec)

Recall that for any integer `N`, the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as 0. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
|------------|----------------|------------|----------------|-------------|
| th         | p0             | 2          | 20             | 20          |
| th         | p1             | 0          | 0              | 0           |

2 rows in set (0.00 sec)

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like 0 for this type of partitioning as well.

## 20.3. Partition Management

MySQL 5.1 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` command (see [Section 12.1.4, “ALTER TABLE Syntax”](#), for syntax definitions). There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see [Section 20.3.1, “Management of RANGE and LIST Partitions”](#).
- For a discussion of managing `HASH` and `KEY` partitions, see [Section 20.3.2, “Management of HASH and KEY Partitions”](#).
- See [Section 20.3.4, “Obtaining Information About Partitions”](#), for a discussion of mechanisms provided in MySQL 5.1 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see [Section 20.3.3, “Maintenance of Partitions”](#).

### Note

In MySQL 5.1, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

The statement `ALTER TABLE ... PARTITION BY ...` is available and is functional beginning with MySQL 5.1.6; previously in MySQL 5.1, this was accepted as valid syntax, but the statement did nothing.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` command with a *partition\_options* clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. For example, suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(YEAR(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990),
 PARTITION p1 VALUES LESS THAN (1995),
 PARTITION p2 VALUES LESS THAN (2000),
 PARTITION p3 VALUES LESS THAN (2005)
);
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`

In MySQL 5.1.7 and earlier MySQL 5.1 releases, `ALTER TABLE ... ENGINE = ...` removed all partitioning from the affected table. Beginning with MySQL 5.1.8, this statement changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. As of MySQL 5.1.8, use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See [Section 12.1.4, "ALTER TABLE Syntax"](#).

### Important

Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITIONS`).

## 20.3.1. Management of RANGE and LIST Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see [Section 20.3.2, "Management of HASH and KEY Partitions"](#). Dropping a `RANGE` or `LIST` partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with a `DROP PARTITION` clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
-> PARTITION BY RANGE(YEAR(purchased)) (
-> PARTITION p0 VALUES LESS THAN (1990),
-> PARTITION p1 VALUES LESS THAN (1995),
-> PARTITION p2 VALUES LESS THAN (2000),
-> PARTITION p3 VALUES LESS THAN (2005)
->);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
-> (1, 'desk organiser', '2003-10-15'),
-> (2, 'CD player', '1993-11-05'),
-> (3, 'TV set', '1996-03-10'),
-> (4, 'bookcase', '1982-01-10'),
-> (5, 'exercise bike', '2004-05-09'),
-> (6, 'sofa', '1987-06-05'),
-> (7, 'popcorn maker', '2001-11-22'),
-> (8, 'aquarium', '1992-08-04'),
-> (9, 'study desk', '1984-09-16'),
-> (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
-> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+-----+-----+-----+
| id | name | purchased |
+-----+-----+-----+
| 3 | TV set | 1996-03-10 |
| 10 | lava lamp | 1998-12-25 |
+-----+-----+-----+
```

```
+-----+-----+-----+
2 rows in set (0.00 sec)
```

To drop the partition named `p2`, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

Note: In MySQL 5.1, the `NDBCLUSTER` storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```
mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Because of this, the requirement was added in MySQL 5.1.10 that you have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` command. (See [Section 12.2.9, “TRUNCATE Syntax”](#).)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in [Section 12.1.4, “ALTER TABLE Syntax”](#), for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` command, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
***** 1. row *****
 Table: tr
Create Table: CREATE TABLE `tr` (
 `id` int(11) default NULL,
 `name` varchar(50) default NULL,
 `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
 PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
 PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
+-----+-----+-----+
| id | name | purchased |
+-----+-----+-----+
11	pencil holder	1995-07-12
1	desk organiser	2003-10-15
5	exercise bike	2004-05-09
7	popcorn maker	2001-11-22
+-----+-----+-----+
4 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

Note that the number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See [Section 20.2.2, “LIST Partitioning”](#), for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. For ex-

ample, suppose that you have a partitioned table containing membership data for your organisation, which is defined as follows:

```
CREATE TABLE members (
 id INT,
 fname VARCHAR(25),
 lname VARCHAR(25),
 dob DATE
)
PARTITION BY RANGE(YEAR(dob)) (
 PARTITION p0 VALUES LESS THAN (1970),
 PARTITION p1 VALUES LESS THAN (1980),
 PARTITION p2 VALUES LESS THAN (1990)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the `members` table to accommodate new members born in the years 1990-1999 as shown here:

```
ALTER TABLE ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

### Important

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions will result in an error as shown here:

```
mysql> ALTER TABLE members
> ADD PARTITION (
> PARTITION p3 VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly >
increasing for each partition
```

In a similar fashion, you can add new partitions to a table that is partitioned by `LIST`. For example, given a table defined like so:

```
CREATE TABLE tt (
 id INT,
 data INT
)
PARTITION BY LIST(data) (
 PARTITION p0 VALUES IN (5, 10, 15),
 PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values 7, 14, and 21 as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Note that you *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
> (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant >
in list partitioning
```

Because any rows with the `data` column value 12 have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes 12 in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1` — and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

Beginning with MySQL 5.1.6, you can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 hired DATE NOT NULL
)
PARTITION BY RANGE(YEAR(hired)) (
 PARTITION p1 VALUES LESS THAN (1991),
 PARTITION p2 VALUES LESS THAN (1996),
 PARTITION p3 VALUES LESS THAN (2001),
 PARTITION p4 VALUES LESS THAN (2005)
);
```

```
ALTER TABLE employees ADD PARTITION (
 PARTITION p5 VALUES LESS THAN (2010),
 PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving [RANGE](#) partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
 Table: members
Create Table: CREATE TABLE `members` (
 `id` int(11) default NULL,
 `fname` varchar(25) default NULL,
 `lname` varchar(25) default NULL,
 `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(dob)) (
 PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
 PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
 PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM,
 PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` in order to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
 PARTITION s0 VALUES LESS THAN (1960),
 PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can return the `members` table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
 PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is:

```
ALTER TABLE tbl_name
 REORGANIZE PARTITION partition_list
 INTO (partition_definitions);
```

Here, `tbl_name` is the name of the partitioned table, and `partition_list` is a comma-separated list of names of one or more existing partitions to be changed. `partition_definitions` is a comma-separated list of new partition definitions, which follow the same rules as for the `partition_definitions` list used in `CREATE TABLE` (see [Section 12.1.10, "CREATE TABLE Syntax"](#)). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
 PARTITION m0 VALUES LESS THAN (1980),
 PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only non-conflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
 PARTITION p1 VALUES IN (6, 18),
 PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` clauses used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by `RANGE`) or sets of values (when reorganizing tables partitioned by `LIST`).

### Note

Prior to MySQL 5.1.4, you could not reuse the names of existing partitions in the `INTO` clause, even when those partitions were being dropped or redefined. See [Section C.1.24, “Changes in MySQL 5.1.4 \(21 December 2005\)”](#), for more information.

- The combination of partitions in the `partition_definitions` list should account for the same range or set of values overall as the combined partitions named in the `partition_list`.

For instance, in the `members` table used as an example in this section, partitions `p1` and `p2` together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip over range partitions.

For instance, you could not reorganize the `members` table used as an example in this section using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use `REORGANIZE PARTITION` to change the table's partitioning type; that is, you cannot (for example) change `RANGE` partitions to `HASH` partitions or *vice versa*. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`. For example:

```
ALTER TABLE members
PARTITION BY HASH(YEAR(dob))
PARTITIONS 8;
```

## 20.3.2. Management of `HASH` and `KEY` Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see [Section 20.3.1, “Management of `RANGE` and `LIST` Partitions”](#).

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` command. For example, suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
 id INT,
 fname VARCHAR(30),
 lname VARCHAR(30),
 signed DATE
)
PARTITION BY HASH(MONTH(signed))
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
-> id INT,
-> fname VARCHAR(30),
-> lname VARCHAR(30),
```

```

-> signed DATE
->)
-> PARTITION BY LINEAR KEY(signed)
-> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_1k COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0 Duplicates: 0 Warnings: 0

```

Note that the number following `COALESCE PARTITION` is the number of partitions to merge into the remainder — in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```

mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead

```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```

ALTER TABLE clients ADD PARTITION PARTITIONS 6;

```

### 20.3.3. Maintenance of Partitions

MySQL 5.1 does not support the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, or `REPAIR TABLE` for partitioned tables. However, there are alternatives available for performing partitioning maintenance tasks.

Beginning with MySQL 5.1.5, you can rebuild partitions using `ALTER TABLE ... REBUILD PARTITION`, which has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation. You can rebuild a one or more partitions belonging to the same table at one time using this statement, as shown in these examples:

```

ALTER TABLE t1 REBUILD PARTITION p1;
ALTER TABLE t1 REBUILD PARTITION p0, p2;

```

Executing the first statement rebuilds the partition named `p1` from the table `t1`. Performing the second statement rebuilds partitions `p0` and `p2` from table `t1`.

`ALTER TABLE ... REORGANIZE PARTITION` also causes partition files to be rebuilt.

The statements `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` were also introduced in MySQL 5.1.5 for the purpose of, respectively, analyzing, checking, optimizing, and repairing individual or multiple partitions. Support for these statements was removed in MySQL 5.1.24. ([Bug#20129](#))

To accomplish these tasks, you can use `mysqlcheck` or, with partitioned `MyISAM` tables, you can use `myisamchk`. See [Section 4.5.3, “mysqlcheck — A Table Maintenance and Repair Program”](#), and [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#), for more information.

### 20.3.4. Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. These include:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```

mysql> SHOW CREATE TABLE trb3\G
***** 1. row *****
 Table: trb3
Create Table: CREATE TABLE `trb3` (
 `id` int(11) default NULL,
 `name` varchar(50) default NULL,
 `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (

```

```

PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)

```

### Note

In early MySQL 5.1 releases, the `PARTITIONS` clause was not shown for tables partitioned by `HASH` or `KEY`. This issue was fixed in MySQL 5.1.6.

`SHOW TABLE STATUS` works with partitioned tables. Beginning with MySQL 5.1.9, its output is the same as that for non-partitioned tables, except that the `Create_options` column contains the string `partitioned`. In MySQL 5.1.8 and earlier, the `Engine` column always contained the value `PARTITION`; beginning with MySQL 5.1.9, this column contains the name of the storage engine used by all partitions of the table. (See [Section 12.5.4.28, “SHOW TABLE STATUS Syntax”](#), for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See [Section 26.19, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#).

Beginning with MySQL 5.1.5, it is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN PARTITIONS`. The `PARTITIONS` keyword adds a `partitions` column to the output of `EXPLAIN` listing the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` defined and populated as follows:

```

CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
 PARTITION p0 VALUES LESS THAN (3),
 PARTITION p1 VALUES LESS THAN (7),
 PARTITION p2 VALUES LESS THAN (9),
 PARTITION p3 VALUES LESS THAN (11)
);

INSERT INTO trb1 VALUES
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
(10, 'lava lamp', '1998-12-25');

```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: trb1
 partitions: p0,p1,p2,p3
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 10
 Extra: Using filesort

```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: trb1
 partitions: p0,p1
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 10
 Extra: Using where

```

`EXPLAIN PARTITIONS` provides information about keys used and possible keys, just as with the standard `EXPLAIN SELECT`

statement:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10 Duplicates: 0 Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: trb1
 partitions: p0,p1
 type: range
possible_keys: PRIMARY
 key: PRIMARY
 key_len: 4
 ref: NULL
 rows: 7
 Extra: Using where
```

You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN ... SELECT` statement. Attempting to do so produces a syntax error.
- If `EXPLAIN PARTITIONS` is used to examine a query against a non-partitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

See also [Section 12.3.2, “EXPLAIN Syntax”](#).

## 20.4. Partition Pruning

This section discusses *partition pruning*, an optimization which was implemented for partitioned tables in MySQL 5.1.6. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. For example, suppose you have a partitioned table `t1` defined by this statement:

```
CREATE TABLE t1 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY RANGE(region_code) (
 PARTITION p0 VALUES LESS THAN (64),
 PARTITION p1 VALUES LESS THAN (128),
 PARTITION p2 VALUES LESS THAN (192)
 PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Consider the case where you wish to obtain results from a query such as this one:

```
SELECT fname, lname, postcode, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much more time and effort in finding matching rows than it is to scan all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing a query, execution of the query can be an order of magnitude faster than the same query against a non-partitioned table containing the same column definitions and data.

The query optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following:

- `partition_column = constant`
- `partition_column IN (constant1, constant2, ..., constantN)`

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equals sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (125, 126, 127, 128, 129, 130)`. Then the optimizer can determine that the first three values in the list are found in partition `p1`, the remaining three values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` or `TO_DAYS()` function.

### Note

We plan to add pruning support in a future MySQL release for additional functions that act on a `DATE` or `DATETIME` value, return an integer, and are increasing or decreasing.

For example, suppose that table `t2`, defined as shown here, is partitioned on a `DATE` column:

```
CREATE TABLE t2 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY RANGE(YEAR(dob)) (
 PARTITION d0 VALUES LESS THAN (1970),
 PARTITION d1 VALUES LESS THAN (1975),
 PARTITION d2 VALUES LESS THAN (1980),
 PARTITION d3 VALUES LESS THAN (1985),
 PARTITION d4 VALUES LESS THAN (1990),
 PARTITION d5 VALUES LESS THAN (2000),
 PARTITION d6 VALUES LESS THAN (2005),
 PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following queries on `t2` can make use of partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';
SELECT * FROM t2 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';
SELECT * FROM t2 WHERE YEAR(dob)
 IN (1979, 1980, 1983, 1985, 1986, 1988);
SELECT * FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last query, the optimizer can also act as follows:

1. Find the partition containing the low end of the range.  
`YEAR('1984-06-21')` yields the value `1984`, which is found in partition `d3`.
2. Find the partition containing the high end of the range.  
`YEAR('1999-06-21')` evaluates to `1999`, which is found in partition `d5`.
3. Scan only these two partitions and any partitions that may lie between them.

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
 PARTITION r0 VALUES IN (1, 3),
 PARTITION r1 VALUES IN (2, 5, 8),
 PARTITION r2 VALUES IN (4, 9),
 PARTITION r3 VALUES IN (6, 7, 10)
```

```
);
```

For a query such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

Any query such as this one can be pruned:

```
SELECT * FROM t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

### Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this query:

```
SELECT * FROM t4 WHERE region_code BETWEEN 4 AND 8;
```

The range in the `WHERE` clause covers 5 values (4, 5, 6, 7, 8), but `t4` has only 4 partitions. This means that the previous query cannot be pruned.

Pruning can be used only on integer columns of tables partitioned by `HASH` or `KEY`. For example, this query on table `t4` cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

## 20.5. Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support, as listed here:

- **Prohibited constructs.** Beginning with MySQL 5.1.12, the following constructs are not permitted in partitioning expressions:
  - Stored functions, stored procedures, UDFs, or plugins.
  - Nested function calls. For example, while `MOD()` and `TO_DAYS()` are both permitted in partitioning expressions, an expression such as `MOD(TO_DAYS(datetime_column), 7)` is not allowed.
  - Declared variables or user variables.
 For a list of SQL functions which are permitted in partitioning expressions, see [Section 20.5.3, “Partitioning Limitations Relating to Functions”](#).
- **Arithmetic and logical operators.** Use of the arithmetic operators `+`, `-`, and `*` is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of `[LINEAR] KEY` partitioning, as discussed elsewhere in this chapter — see [Section 20.2, “Partition Types”](#), for more information).

Beginning with MySQL 5.1.23, the `DIV` operator is also supported, and the `/` operator is disallowed. ([Bug#30188](#), [Bug#33182](#))

Beginning with MySQL 5.1.12, the bit operators `|`, `&`, `^`, `<<`, `>>`, and `~` are not permitted in partitioning expressions.

- **Server SQL mode.** Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in [Section 5.1.7, “SQL Modes”](#), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables.*
- **Performance considerations.**
  - **Filesystem operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITIONS`, or `REMOVE PARTITIONING`) depend on filesystem operations for their implementation. This means that the speed of these operations is affected by such factors as filesystem type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. For partitioned tables using the `MyISAM` storage engine, increasing `myisam_max_sort_file_size` may improve performance; partitioning and repartitioning operations involving `InnoDB` tables may be made more efficient by enabling `innodb_file_per_table`.
  - **Table locks.** The process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed.
  - **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with `MyISAM` tables than with `InnoDB` or `NDB` tables.
  - **Use of indexes and partition pruning.** As with non-partitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of *partition pruning* can improve performance dramatically. See [Section 20.4, “Partition Pruning”](#), for more information.
  - **Performance with `LOAD DATA`.** Prior to MySQL 5.1.23, `LOAD DATA` performed very poorly when importing into partitioned tables. The statement now uses buffering to improve performance; however, the buffer uses 130 KB memory per partition to achieve this. ([Bug#26527](#))
- **Maximum number of partitions.** The maximum number of partitions possible for a given table is 1024. This includes subpartitions.

If, when creating tables with a very large number of partitions (but which is less than the maximum stated previously), you encounter an error message such as `GOT ERROR 24 FROM STORAGE ENGINE`, this means that you may need to increase the value of the `open_files_limit` system variable. See [Section B.1.2.18, “‘FILE’ NOT FOUND and Similar Errors”](#).

- **Foreign keys not supported.** Partitioned tables do not support foreign keys. This means that:
  1. Definitions of tables employing user-defined partitioning may not contain foreign key references to other tables.
  2. No table definition may contain a foreign key reference to a partitioned table.
 The scope of these restrictions includes tables that use the `InnoDB` storage engine.
- **`ALTER TABLE ... ORDER BY`.** An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.
- **FULLTEXT indexes.** Partitioned tables do not support `FULLTEXT` indexes. This includes partitioned tables employing the `MyISAM` storage engine.
- **Spatial columns.** Columns with spatial data types such as `POINT` or `GEOMETRY` cannot be used in partitioned tables.
- **Temporary tables.** As of MySQL 5.1.8, temporary tables cannot be partitioned. ([Bug#17497](#))
- **Log tables.** Beginning with MySQL 5.1.20, it is no longer possible to partition the log tables; beginning with that version, an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error. ([Bug#27816](#))
- **Data type of partitioning key.** A partitioning key must be either an integer column or an expression that resolves to an integer. The column or expression value may also be `NULL`. (See [Section 20.2.6, “How MySQL Partitioning Handles `NULL` Values”](#).)

The lone exception to this restriction occurs when partitioning by `[LINEAR] KEY`, where it is possible to use columns of other types as partitioning keys, because MySQL’s internal key-hashing functions produce the correct data type from these types. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;
```

This exception does *not* apply to `BLOB` or `TEXT` column types.

- **Subqueries.** A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.
- **Subpartitions.** Subpartitions are limited to `HASH` or `KEY` partitioning. `HASH` and `KEY` partitions cannot be subpartitioned.
- **Key caches not supported.** Key caches are not supported for partitioned tables. The `LOAD CACHE` and `LOAD INDEX INTO CACHE` statements, when you attempt to use them on tables having user-defined partitioning, fail with the errors `THE STORAGE ENGINE FOR THE TABLE DOESN'T SUPPORT ASSIGN_TO_KEYCACHE` and `THE STORAGE ENGINE FOR THE TABLE DOESN'T SUPPORT PRELOAD_KEYS`, respectively.
- **DELAYED option not supported.** Use of `INSERT DELAYED` to insert rows into a partitioned table is not supported. Beginning with MySQL 5.1.23, attempting to do so fails with an error. ([Bug#31210](#))
- **DATA DIRECTORY and INDEX DIRECTORY options.** `DATA DIRECTORY` and `INDEX DIRECTORY` are subject to the following restrictions when used with partitioned tables:
  - Beginning with MySQL 5.1.23, table-level `DATA DIRECTORY` and `INDEX DIRECTORY` are ignored. ([Bug#32091](#))
  - On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions ([Bug#30459](#)).

## 20.5.1. Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression*. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1),
 UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
-> col1 INT NOT NULL,
-> col2 DATE NOT NULL,
-> col3 INT NOT NULL,
-> col4 INT NOT NULL,
-> UNIQUE KEY (col1, col2),
-> UNIQUE KEY (col3)
->)
-> PARTITION BY HASH(col1 + col3)
-> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION
```

The `CREATE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition;

```
mysql> CREATE TABLE t3 (
-> col1 INT NOT NULL,
-> col2 DATE NOT NULL,
-> col3 INT NOT NULL,
-> col4 INT NOT NULL,
-> UNIQUE KEY (col1, col2, col3),
-> UNIQUE KEY (col3)
->)
-> PARTITION BY HASH(col3)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```
CREATE TABLE t4 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t5 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col3),
 UNIQUE KEY(col2)
)
PARTITION BY HASH(YEAR(col2))
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```
CREATE TABLE t6 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t7 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col2, col4),
 UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;
```

If a table has no unique keys — this includes having no primary key — then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider given the partitioned table defined as shown here:

```
mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
-> PARTITION BY RANGE(c1) (
```

```

-> PARTITION p0 VALUES LESS THAN (10),
-> PARTITION p1 VALUES LESS THAN (20),
-> PARTITION p2 VALUES LESS THAN (30),
-> PARTITION p3 VALUES LESS THAN (40)
->);
Query OK, 0 rows affected (0.12 sec)

```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```

possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0 Duplicates: 0 Warnings: 0

use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0 Duplicates: 0 Warnings: 0

drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0 Duplicates: 0 Warnings: 0

```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```

fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION

```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing non-partitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` defined as shown here:

```

mysql> CREATE TABLE np_pk (
-> id INT NOT NULL AUTO_INCREMENT,
-> name VARCHAR(50),
-> added DATE,
-> PRIMARY KEY (id)
->);
Query OK, 0 rows affected (0.08 sec)

```

The following `ALTER TABLE` statements fails with an error, because the `added` column is not part of any unique key in the table:

```

mysql> ALTER TABLE np_pk
-> PARTITION BY HASH(TO_DAYS(added))
-> PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION

```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```

mysql> ALTER TABLE np_pk
-> PARTITION BY HASH(id)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0

```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

We are working to remove this limitation in a future MySQL release series.

## 20.5.2. Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

**MERGE storage engine.** User-defined partitioning and the `MERGE` storage engine are not compatible. Tables using the `MERGE` storage engine cannot be partitioned. Partitioned tables cannot be merged.

**FEDERATED storage engine.** Partitioning of `FEDERATED` tables is not supported. Beginning with MySQL 5.1.15, it is not possible to create partitioned `FEDERATED` tables at all. We are working to remove this limitation in a future MySQL release.

**CSV storage engine.** Partitioned tables using the `CSV` storage engine are not supported. Starting with MySQL 5.1.12, it is not possible to create partitioned `CSV` tables at all.

**BLACKHOLE storage engine.** Prior to MySQL 5.1.6, tables using the `BLACKHOLE` storage engine also could not be partitioned.

**NDB storage engine (MySQL Cluster).** Partitioning by `KEY` (or `LINEAR KEY`) is the only type of partitioning supported for the `NDB` storage engine. Beginning with MySQL 5.1.12, it is not possible to create a Cluster table using any partitioning type other than `[LINEAR] KEY`, and attempting to do so fails with an error.

**Upgrading partitioned tables.** When performing an upgrade, tables which are partitioned by `KEY` and which use any storage engine other than `NDBCLUSTER` must be dumped and reloaded.

**Same storage engine for all partitions.** All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do *not* specify any engine for *any* partition or subpartition
- Specify the engine for *all* partitions or subpartitions

We are working to remove this limitation in a future MySQL release.

### 20.5.3. Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Beginning with MySQL 5.1.12, only the following MySQL functions are supported in partitioning expressions:

- `ABS()`
- `CEILING()` (see `CEILING()` and `FLOOR()`, immediately following this list)
- `DAY()`
- `DAYOFMONTH()`
- `DAYOFWEEK()`
- `DAYOFYEAR()`
- `DATEDIFF()`
- `EXTRACT()`
- `FLOOR()` (see `CEILING()` and `FLOOR()`, immediately following this list)
- `HOUR()`
- `MICROSECOND()`
- `MINUTE()`
- `MOD()`
- `MONTH()`
- `QUARTER()`
- `SECOND()`
- `TIME_TO_SEC()`
- `TO_DAYS()`
- `WEEKDAY()`
- `YEAR()`
- `YEARWEEK()`

**Note**

**CEILING()** and **FLOOR()**. Each of these functions returns an integer only if it is passed an integer argument. This means, for example, that the following **CREATE TABLE** statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST(FLOOR(c))(
-> PARTITION p0 VALUES IN (1,3,5),
-> PARTITION p1 VALUES IN (2,4,6)
->);
ERROR 1490 (HY000): THE PARTITION FUNCTION RETURNS THE WRONG TYPE
```

See [Section 11.5.2, “Mathematical Functions”](#), for more information about the return types of these functions.

---

# Chapter 21. Spatial Extensions

MySQL supports spatial extensions to allow the generation, storage, and analysis of geographic features. These features are available for `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` tables.

For spatial columns, `MyISAM` supports both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in [Section 12.1.7, “CREATE INDEX Syntax”](#).

This chapter covers the following topics:

- The basis of these spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

## Additional resources

- The Open Geospatial Consortium publishes the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>.
- If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: <http://forums.mysql.com/list.php?23>.

## 21.1. Introduction to MySQL Spatial Support

MySQL implements spatial extensions following the specification of the Open Geospatial Consortium (OGC). This is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data. The OGC maintains a Web site at <http://www.opengis.org/>.

In 1997, the Open Geospatial Consortium published the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>. It contains additional information relevant to this chapter.

MySQL implements a subset of the **SQL with Geometry Types** environment proposed by OGC. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describe a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term **geospatial feature** to refer to geographic features.

**Geometry** is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

This chapter uses all of these terms synonymously: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. Here, the term most commonly used is **geometry**, defined as *a point or an aggregate of points representing anything in the world that has a location*.

## 21.2. The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a Spatial Reference System, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

### 21.2.1. The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- `Geometry` (non-instantiable)
  - `Point` (instantiable)
  - `Curve` (non-instantiable)
    - `LineString` (instantiable)
      - `Line`
      - `LinearRing`
  - `Surface` (non-instantiable)
    - `Polygon` (instantiable)
  - `GeometryCollection` (instantiable)
    - `MultiPoint` (instantiable)
    - `MultiCurve` (non-instantiable)
      - `MultiLineString` (instantiable)
    - `MultiSurface` (non-instantiable)
      - `MultiPolygon` (instantiable)

It is not possible to create objects in non-instantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

`Geometry` is the base class. It is an abstract class. The instantiable subclasses of `Geometry` are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base `Geometry` class has subclasses for `Point`, `Curve`, `Surface`, and `GeometryCollection`:

- `Point` represents zero-dimensional objects.
- `Curve` represents one-dimensional objects, and has subclass `LineString`, with sub-subclasses `Line` and `LinearRing`.
- `Surface` is designed for two-dimensional objects and has subclass `Polygon`.
- `GeometryCollection` has specialized zero-, one-, and two-dimensional collection classes named `MultiPoint`, `MultiLineString`, and `MultiPolygon` for modeling geometries corresponding to collections of `Points`, `LineStrings`, and `Polygons`, respectively. `MultiCurve` and `MultiSurface` are introduced as abstract superclasses that generalize the collection interfaces to handle `Curves` and `Surfaces`.

`Geometry`, `Curve`, `Surface`, `MultiCurve`, and `MultiSurface` are defined as non-instantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

`Point`, `LineString`, `Polygon`, `GeometryCollection`, `MultiPoint`, `MultiLineString`, and `MultiPolygon` are instantiable classes.

## 21.2.2. Class `Geometry`

`Geometry` is the root class of the hierarchy. It is a non-instantiable class but has a number of properties that are common to all geometry values created from any of the `Geometry` subclasses. These properties are described in the following list. Particular subclasses have their own specific properties, described later.

### Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.
- Its **SRID**, or Spatial Reference Identifier. This value identifies the geometry's associated Spatial Reference System that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

- Its **coordinates** in its Spatial Reference System, represented as double-precision (eight-byte) numbers. All non-empty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geocentric** system (coordinates on the Earth's surface) are different things.

- Its **interior, boundary, and exterior**.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (Minimum Bounding Rectangle), or Envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **non-simple**. Geometry values of types (`LineString`, `MultiPoint`, `MultiLineString`) are either simple or non-simple. Each type determines its own assertions for being simple or non-simple.
- Whether the value is **closed** or **not closed**. Geometry values of types (`LineString`, `MultiString`) are either closed or not closed. Each type determines its own assertions for being closed or not closed.
- Whether the value is **empty** or **non-empty**. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a `NULL` value). An empty geometry is defined to be always simple and has an area of 0.
- Its **dimension**. A geometry can have a dimension of -1, 0, 1, or 2:
  - -1 for an empty geometry.
  - 0 for a geometry with no length and no area.
  - 1 for a geometry with non-zero length and zero area.
  - 2 for a geometry with non-zero area.

`Point` objects have a dimension of zero. `LineString` objects have a dimension of 1. `Polygon` objects have a dimension of 2. The dimensions of `MultiPoint`, `MultiLineString`, and `MultiPolygon` objects are the same as the dimensions of the elements they consist of.

## 21.2.3. Class `Point`

A `Point` is a geometry that represents a single location in coordinate space.

### Point Examples

- Imagine a large-scale map of the world with many cities. A `Point` object could represent each city.
- On a city map, a `Point` object could represent a bus stop.

### Point Properties

- X-coordinate value.
- Y-coordinate value.
- `Point` is defined as a zero-dimensional geometry.
- The boundary of a `Point` is the empty set.

## 21.2.4. Class `Curve`

A `Curve` is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of `Curve` define the type of interpolation between points. `Curve` is a non-instantiable class.

### Curve Properties

- A `Curve` has the coordinates of its points.
- A `Curve` is defined as a one-dimensional geometry.
- A `Curve` is simple if it does not pass through the same point twice.
- A `Curve` is closed if its start point is equal to its endpoint.
- The boundary of a closed `Curve` is empty.
- The boundary of a non-closed `Curve` consists of its two endpoints.
- A `Curve` that is simple and closed is a `LinearRing`.

## 21.2.5. Class `LineString`

A `LineString` is a `Curve` with linear interpolation between points.

### LineString Examples

- On a world map, `LineString` objects could represent rivers.
- In a city map, `LineString` objects could represent streets.

### LineString Properties

- A `LineString` has coordinates of segments, defined by each consecutive pair of points.
- A `LineString` is a `Line` if it consists of exactly two points.
- A `LineString` is a `LinearRing` if it is both closed and simple.

## 21.2.6. Class `Surface`

A `Surface` is a two-dimensional geometry. It is a non-instantiable class. Its only instantiable subclass is `Polygon`.

### Surface Properties

- A `Surface` is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple `Surface` as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple `Surface` is the set of closed curves corresponding to its exterior and interior boundaries.

## 21.2.7. Class `Polygon`

A `Polygon` is a planar `Surface` representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the `Polygon`.

### `Polygon` Examples

- On a region map, `Polygon` objects could represent forests, districts, and so on.

### `Polygon` Assertions

- The boundary of a `Polygon` consists of a set of `LinearRing` objects (that is, `LineString` objects that are both simple and closed) that make up its exterior and interior boundaries.
- A `Polygon` has no rings that cross. The rings in the boundary of a `Polygon` may intersect at a `Point`, but only as a tangent.
- A `Polygon` has no lines, spikes, or punctures.
- A `Polygon` has an interior that is a connected point set.
- A `Polygon` may have holes. The exterior of a `Polygon` with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a `Polygon` a simple geometry.

## 21.2.8. Class `GeometryCollection`

A `GeometryCollection` is a geometry that is a collection of one or more geometries of any class.

All the elements in a `GeometryCollection` must be in the same Spatial Reference System (that is, in the same coordinate system). There are no other constraints on the elements of a `GeometryCollection`, although the subclasses of `GeometryCollection` described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a `MultiPoint` may contain only `Point` elements)
- Dimension
- Constraints on the degree of spatial overlap between elements

## 21.2.9. Class `MultiPoint`

A `MultiPoint` is a geometry collection composed of `Point` elements. The points are not connected or ordered in any way.

### `MultiPoint` Examples

- On a world map, a `MultiPoint` could represent a chain of small islands.
- On a city map, a `MultiPoint` could represent the outlets for a ticket office.

### `MultiPoint` Properties

- A `MultiPoint` is a zero-dimensional geometry.
- A `MultiPoint` is simple if no two of its `Point` values are equal (have identical coordinate values).
- The boundary of a `MultiPoint` is the empty set.

## 21.2.10. Class `MultiCurve`

A `MultiCurve` is a geometry collection composed of `Curve` elements. `MultiCurve` is a non-instantiable class.

### MultiCurve Properties

- A `MultiCurve` is a one-dimensional geometry.
- A `MultiCurve` is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A `MultiCurve` boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a `MultiCurve` if it is in the boundaries of an odd number of `MultiCurve` elements.
- A `MultiCurve` is closed if all of its elements are closed.
- The boundary of a closed `MultiCurve` is always empty.

## 21.2.11. Class `MultiLineString`

A `MultiLineString` is a `MultiCurve` geometry collection composed of `LineString` elements.

### MultiLineString Examples

- On a region map, a `MultiLineString` could represent a river system or a highway system.

## 21.2.12. Class `MultiSurface`

A `MultiSurface` is a geometry collection composed of surface elements. `MultiSurface` is a non-instantiable class. Its only instantiable subclass is `MultiPolygon`.

### MultiSurface Assertions

- Two `MultiSurface` surfaces have no interiors that intersect.
- Two `MultiSurface` elements have boundaries that intersect at most at a finite number of points.

## 21.2.13. Class `MultiPolygon`

A `MultiPolygon` is a `MultiSurface` object composed of `Polygon` elements.

### MultiPolygon Examples

- On a region map, a `MultiPolygon` could represent a system of lakes.

### MultiPolygon Assertions

- A `MultiPolygon` has no two `Polygon` elements with interiors that intersect.
- A `MultiPolygon` has no two `Polygon` elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A `MultiPolygon` may not have cut lines, spikes, or punctures. A `MultiPolygon` is a regular, closed point set.
- A `MultiPolygon` that has more than one `Polygon` has an interior that is not connected. The number of connected components of the interior of a `MultiPolygon` is equal to the number of `Polygon` values in the `MultiPolygon`.

### MultiPolygon Properties

- A `MultiPolygon` is a two-dimensional geometry.
- A `MultiPolygon` boundary is a set of closed curves (`LineString` values) corresponding to the boundaries of its `Polygon` elements.

- Each [Curve](#) in the boundary of the [MultiPolygon](#) is in the boundary of exactly one [Polygon](#) element.
- Every [Curve](#) in the boundary of an [Polygon](#) element is in the boundary of the [MultiPolygon](#).

## 21.3. Supported Spatial Data Formats

This section describes the standard spatial data formats that are used to represent geometry objects in queries. They are:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format.

### 21.3.1. Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form.

Examples of WKT representations of geometry objects:

- A [Point](#):

```
POINT(15 20)
```

Note that point coordinates are specified with no separating comma.

- A [LineString](#) with four points:

```
LINestring(0 0, 10 10, 20 25, 50 60)
```

Note that point coordinate pairs are separated by commas.

- A [Polygon](#) with one exterior ring and one interior ring:

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
```

- A [MultiPoint](#) with three [Point](#) values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

- A [MultiLineString](#) with two [LineString](#) values:

```
MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
```

- A [MultiPolygon](#) with two [Polygon](#) values:

```
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
```

- A [GeometryCollection](#) consisting of two [Point](#) values and one [LineString](#):

```
GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINestring(15 15, 20 20))
```

A Backus-Naur grammar that specifies the formal production rules for writing WKT values can be found in the OpenGIS specification document referenced near the beginning of this chapter.

### 21.3.2. Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation for geometric values is defined by the OpenGIS specification. It is also defined in the ISO *SQL/MM Part 3: Spatial* standard.

WKB is used to exchange geometry data as binary streams represented by [BLOB](#) values containing geometric WKB information.

WKB uses one-byte unsigned integers, four-byte unsigned integers, and eight-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 1)` consists of this sequence of 21 bytes (each represented here by two hex digits):

```
010100000000000000000000F03F000000000000F03F
```

The sequence may be broken down into these components:

```
Byte order : 01
WKB type : 01000000
X : 000000000000F03F
Y : 000000000000F03F
```

Component representation is as follows:

- The byte order may be either 1 or 0 to indicate little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.
- The WKB type is a code that indicates the geometry type. Values from 1 through 7 indicate `Point`, `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, `MultiPolygon`, and `GeometryCollection`.
- A `Point` value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values are represented by more complex data structures, as detailed in the OpenGIS specification.

## 21.4. Creating a Spatially Enabled MySQL Database

This section describes the data types you can use for representing spatial data in MySQL, and the functions available for creating and retrieving spatial values.

### 21.4.1. MySQL Spatial Data Types

MySQL has data types that correspond to OpenGIS classes. Some of these types hold single geometry values:

- `GEOMETRY`
- `POINT`
- `LINESTRING`
- `POLYGON`

`GEOMETRY` can store geometry values of any type. The other single-value types (`POINT`, `LINESTRING`, and `POLYGON`) restrict their values to a particular geometry type.

The other data types hold collections of values:

- `MULTIPOINT`
- `MULTILINESTRING`
- `MULTIPOLYGON`
- `GEOMETRYCOLLECTION`

`GEOMETRYCOLLECTION` can store a collection of objects of any type. The other collection types (`MULTIPOINT`, `MULTILINESTRING`, `MULTIPOLYGON`, and `GEOMETRYCOLLECTION`) restrict collection members to those having a particular geometry type.

### 21.4.2. Creating Spatial Values

This section describes how to create spatial values using Well-Known Text and Well-Known Binary functions that are defined in the OpenGIS standard, and using MySQL-specific functions.

### 21.4.2.1. Creating Geometry Values Using WKT Functions

MySQL provides a number of functions that take as input parameters a Well-Known Text representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromText()` accepts a WKT of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromText(wkt[,srid]), GeometryCollectionFromText(wkt[,srid])`  
Constructs a `GEOMETRYCOLLECTION` value using its WKT representation and SRID.
- `GeomFromText(wkt[,srid]), GeometryFromText(wkt[,srid])`  
Constructs a geometry value of any type using its WKT representation and SRID.
- `LineFromText(wkt[,srid]), LineStringFromText(wkt[,srid])`  
Constructs a `LINESTRING` value using its WKT representation and SRID.
- `MLineFromText(wkt[,srid]), MultiLineStringFromText(wkt[,srid])`  
Constructs a `MULTILINESTRING` value using its WKT representation and SRID.
- `MPointFromText(wkt[,srid]), MultiPointFromText(wkt[,srid])`  
Constructs a `MULTIPOINT` value using its WKT representation and SRID.
- `MPolyFromText(wkt[,srid]), MultiPolygonFromText(wkt[,srid])`  
Constructs a `MULTIPOLYGON` value using its WKT representation and SRID.
- `PointFromText(wkt[,srid])`  
Constructs a `POINT` value using its WKT representation and SRID.
- `PolyFromText(wkt[,srid]), PolygonFromText(wkt[,srid])`  
Constructs a `POLYGON` value using its WKT representation and SRID.

The OpenGIS specification also defines the following optional functions, which MySQL does not implement. These functions construct `Polygon` or `MultiPolygon` values based on the WKT representation of a collection of rings or closed `LineString` values. These values may intersect.

- `BdMPolyFromText(wkt,srid)`  
Constructs a `MultiPolygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.
- `BdPolyFromText(wkt,srid)`  
Constructs a `Polygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

### 21.4.2.2. Creating Geometry Values Using WKB Functions

MySQL provides a number of functions that take as input parameters a `BLOB` containing a Well-Known Binary representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromWKB()` accepts a WKB of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromWKB(wkb[,srid]), GeometryCollectionFromWKB(wkb[,srid])`

Constructs a `GEOMETRYCOLLECTION` value using its WKB representation and SRID.

- `GeomFromWKB(wkb [, srid])`, `GeometryFromWKB(wkb [, srid])`

Constructs a geometry value of any type using its WKB representation and SRID.

- `LineFromWKB(wkb [, srid])`, `LineStringFromWKB(wkb [, srid])`

Constructs a `LINestring` value using its WKB representation and SRID.

- `MLineFromWKB(wkb [, srid])`, `MultiLineStringFromWKB(wkb [, srid])`

Constructs a `MULTILINestring` value using its WKB representation and SRID.

- `MPointFromWKB(wkb [, srid])`, `MultiPointFromWKB(wkb [, srid])`

Constructs a `MULTIPOINT` value using its WKB representation and SRID.

- `MPolyFromWKB(wkb [, srid])`, `MultiPolygonFromWKB(wkb [, srid])`

Constructs a `MULTIPOLYGON` value using its WKB representation and SRID.

- `PointFromWKB(wkb [, srid])`

Constructs a `POINT` value using its WKB representation and SRID.

- `PolyFromWKB(wkb [, srid])`, `PolygonFromWKB(wkb [, srid])`

Constructs a `POLYGON` value using its WKB representation and SRID.

The OpenGIS specification also describes optional functions for constructing `Polygon` or `MultiPolygon` values based on the WKB representation of a collection of rings or closed `LineString` values. These values may intersect. MySQL does not implement these functions:

- `BdMPolyFromWKB(wkb, srid)`

Constructs a `MultiPolygon` value from a `MultiLineString` value in WKB format containing an arbitrary collection of closed `LineString` values.

- `BdPolyFromWKB(wkb, srid)`

Constructs a `Polygon` value from a `MultiLineString` value in WKB format containing an arbitrary collection of closed `LineString` values.

### 21.4.2.3. Creating Geometry Values Using MySQL-Specific Functions

MySQL provides a set of useful non-standard functions for creating geometry WKB representations. The functions described in this section are MySQL extensions to the OpenGIS specification. The results of these functions are `BLOB` values containing WKB representations of geometry values with no SRID. The results of these functions can be substituted as the first argument for any function in the `GeomFromWKB()` function family.

- `GeometryCollection(g1, g2, ...)`

Constructs a WKB `GeometryCollection`. If any argument is not a well-formed WKB representation of a geometry, the return value is `NULL`.

- `LineString(pt1, pt2, ...)`

Constructs a WKB `LineString` value from a number of WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is `NULL`. If the number of `Point` arguments is less than two, the return value is `NULL`.

- `MultiLineString(ls1, ls2, ...)`

Constructs a WKB `MultiLineString` value using WKB `LineString` arguments. If any argument is not a WKB `LineString`, the return value is `NULL`.

- `MultiPoint(pt1, pt2, ...)`

Constructs a WKB `MultiPoint` value using WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is `NULL`.

- `MultiPolygon(poly1,poly2,...)`

Constructs a WKB `MultiPolygon` value from a set of WKB `Polygon` arguments. If any argument is not a WKB `Polygon`, the return value is `NULL`.

- `Point(x,y)`

Constructs a WKB `Point` using its coordinates.

- `Polygon(ls1,ls2,...)`

Constructs a WKB `Polygon` value from a number of WKB `LineString` arguments. If any argument does not represent the WKB of a `LinearRing` (that is, not a closed and simple `LineString`) the return value is `NULL`.

### 21.4.3. Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Currently, spatial columns are supported for `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` tables. See also the annotations about spatial indexes under [Section 21.6.1, “Creating Spatial Indexes”](#).

- Use the `CREATE TABLE` statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

- Use the `ALTER TABLE` statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

### 21.4.4. Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values into internal geometry format:

- Perform the conversion directly in the `INSERT` statement:

```
INSERT INTO geom VALUES (GeomFromText('POINT(1 1)'));
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (GeomFromText(@g));
```

- Perform the conversion prior to the `INSERT`:

```
SET @g = GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomFromText(@g));
```

The preceding examples all use `GeomFromText()` to create geometry values. You can also use type-specific functions:

```

SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (PolygonFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomCollFromText(@g));

```

Note that if a client application program wants to use WKB representations of geometry values, it is responsible for sending correctly formed WKB in queries to the server. However, there are several ways of satisfying this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

```

mysql> INSERT INTO geom VALUES
-> (GeomFromWKB(0x010100000000000000000000F03F0000000000F03F));

```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

```

INSERT INTO geom VALUES (GeomFromWKB(?))

```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string()` and include the result in a query string that is sent to the server. See [Section 28.2.3.53](#), “`mysql_real_escape_string()`”.

## 21.4.5. Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them into WKT or WKB format.

- Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```

CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;

```

- Fetching spatial data in WKT format:

The `AsText()` function converts a geometry from internal format into a WKT string.

```

SELECT AsText(g) FROM geom;

```

- Fetching spatial data in WKB format:

The `AsBinary()` function converts a geometry from internal format into a `BLOB` containing the WKB value.

```

SELECT AsBinary(g) FROM geom;

```

## 21.5. Analyzing Spatial Information

After populating spatial columns with values, you are ready to query and analyze them. MySQL provides a set of functions to perform various operations on spatial data. These functions can be grouped into four major categories according to the type of operation they perform:

- Functions that convert geometries between various formats
- Functions that provide access to qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

Spatial analysis functions can be used in many contexts, such as:

- Any interactive SQL program, such as `mysql` or MySQL Query Browser
- Application programs written in any language that supports a MySQL client API

## 21.5.1. Geometry Format Conversion Functions

MySQL supports the following functions for converting geometry values between internal format and either WKT or WKB format:

- `AsBinary(g), AsWKB(g)`

Converts a value in internal geometry format to its WKB representation and returns the binary result.

```
SELECT AsBinary(g) FROM geom;
```

- `AsText(g), AsWKT(g)`

Converts a value in internal geometry format to its WKT representation and returns the string result.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(GeomFromText(@g));
+-----+
| AsText(GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,2 2,3 3) |
+-----+
```

- `GeomFromText(wkt[, srid])`

Converts a string value from its WKT representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromText()` and `LineFromText()`. See [Section 21.4.2.1, “Creating Geometry Values Using WKT Functions”](#).

- `GeomFromWKB(wkb[, srid])`

Converts a binary value from its WKB representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromWKB()` and `LineFromWKB()`. See [Section 21.4.2.2, “Creating Geometry Values Using WKB Functions”](#).

## 21.5.2. Geometry Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return `NULL` if the argument is of an incorrect geometry type. For example, `Area()` returns `NULL` if the object type is neither `Polygon` nor `MultiPolygon`.

### 21.5.2.1. General Geometry Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- `Dimension(g)`

Returns the inherent dimension of the geometry value `g`. The result can be `-1`, `0`, `1`, or `2`. The meaning of these values is given in [Section 21.2.2, “Class Geometry”](#).

```
mysql> SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+-----+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

- `Envelope(g)`

Returns the Minimum Bounding Rectangle (MBR) for the geometry value `g`. The result is returned as a `Polygon` value.

The polygon is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT AsText(Envelope(GeomFromText('LineString(1 1,2 2)')));
+-----+
| AsText(Envelope(GeomFromText('LineString(1 1,2 2)')) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

- `GeometryType(g)`

Returns as a string the name of the geometry type of which the geometry instance *g* is a member. The name corresponds to one of the instantiable `Geometry` subclasses.

```
mysql> SELECT GeometryType(GeomFromText('POINT(1 1)'));
+-----+
| GeometryType(GeomFromText('POINT(1 1)')) |
+-----+
| POINT |
+-----+
```

- `SRID(g)`

Returns an integer indicating the Spatial Reference System ID for the geometry value *g*.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

```
mysql> SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
+-----+
| SRID(GeomFromText('LineString(1 1,2 2)',101)) |
+-----+
| 101 |
+-----+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- `Boundary(g)`

Returns a geometry that is the closure of the combinatorial boundary of the geometry value *g*.

- `IsEmpty(g)`

Returns 1 if the geometry value *g* is the empty geometry, 0 if it is not empty, and -1 if the argument is `NULL`. If the geometry is empty, it represents the empty point set.

- `IsSimple(g)`

Currently, this function is a placeholder and should not be used. If implemented, its behavior will be as described in the next paragraph.

Returns 1 if the geometry value *g* has no anomalous geometric points, such as self-intersection or self-tangency. `IsSimple()` returns 0 if the argument is not simple, and -1 if it is `NULL`.

The description of each instantiable geometric class given earlier in the chapter includes the specific conditions that cause an instance of that class to be classified as not simple. (See [Section 21.2.1, “The Geometry Class Hierarchy”](#).)

## 21.5.2.2. Point Functions

A `Point` consists of X and Y coordinates, which may be obtained using the following functions:

- `X(p)`

Returns the X-coordinate value for the point *p* as a double-precision number.

```
mysql> SET @pt = 'Point(56.7 53.34)';
mysql> SELECT X(GeomFromText(@pt));
+-----+
| X(GeomFromText(@pt)) |
+-----+
```

```
|----- 56.7 |
+-----+
```

- `Y(p)`

Returns the Y-coordinate value for the point *p* as a double-precision number.

```
mysql> SET @pt = 'Point(56.7 53.34)';
mysql> SELECT Y(GeomFromText(@pt));
+-----+
| Y(GeomFromText(@pt)) |
+-----+
| 53.34 |
+-----+
```

### 21.5.2.3. LineString Functions

A `LineString` consists of `Point` values. You can extract particular points of a `LineString`, count the number of points that it contains, or obtain its length.

- `EndPoint(ls)`

Returns the `Point` that is the endpoint of the `LineString` value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(EndPoint(GeomFromText(@ls)));
+-----+
| AsText(EndPoint(GeomFromText(@ls))) |
+-----+
| POINT(3 3) |
+-----+
```

- `GLength(ls)`

Returns as a double-precision number the length of the `LineString` value *ls* in its associated spatial reference.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT GLength(GeomFromText(@ls));
+-----+
| GLength(GeomFromText(@ls)) |
+-----+
| 2.8284271247462 |
+-----+
```

`GLength()` is a non-standard name. It corresponds to the OpenGIS `Length()` function.

- `NumPoints(ls)`

Returns the number of `Point` objects in the `LineString` value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT NumPoints(GeomFromText(@ls));
+-----+
| NumPoints(GeomFromText(@ls)) |
+-----+
| 3 |
+-----+
```

- `PointN(ls,N)`

Returns the *N*-th `Point` in the `LineString` value *ls*. Points are numbered beginning with 1.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(PointN(GeomFromText(@ls),2));
+-----+
| AsText(PointN(GeomFromText(@ls),2)) |
+-----+
| POINT(2 2) |
+-----+
```

- `StartPoint(ls)`

Returns the `Point` that is the start point of the `LineString` value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
```

```
mysql> SELECT AsText(StartPoint(GeomFromText(@ls)));
+-----+
| AsText(StartPoint(GeomFromText(@ls))) |
+-----+
| POINT(1 1) |
+-----+
```

The OpenGIS specification also defines the following function, which MySQL does not implement:

- `IsRing(ls)`

Returns 1 if the `LineString` value *ls* is closed (that is, its `StartPoint()` and `EndPoint()` values are the same) and is simple (does not pass through the same point more than once). Returns 0 if *ls* is not a ring, and -1 if it is `NULL`.

### 21.5.2.4. MultiLineString Functions

These functions return properties of `MultiLineString` values.

- `GLength(mls)`

Returns as a double-precision number the length of the `MultiLineString` value *m*ls. The length of *m*ls is equal to the sum of the lengths of its elements.

```
mysql> SET @m = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT GLength(GeomFromText(@m));
+-----+
| GLength(GeomFromText(@m)) |
+-----+
| 4.2426406871193 |
+-----+
```

`GLength()` is a non-standard name. It corresponds to the OpenGIS `Length()` function.

- `IsClosed(mls)`

Returns 1 if the `MultiLineString` value *m*ls is closed (that is, the `StartPoint()` and `EndPoint()` values are the same for each `LineString` in *m*ls). Returns 0 if *m*ls is not closed, and -1 if it is `NULL`.

```
mysql> SET @m = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT IsClosed(GeomFromText(@m));
+-----+
| IsClosed(GeomFromText(@m)) |
+-----+
| 0 |
+-----+
```

### 21.5.2.5. Polygon Functions

These functions return properties of `Polygon` values.

- `Area(poly)`

Returns as a double-precision number the area of the `Polygon` value *poly*, as measured in its spatial reference system.

```
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT Area(GeomFromText(@poly));
+-----+
| Area(GeomFromText(@poly)) |
+-----+
| 4 |
+-----+
```

- `ExteriorRing(poly)`

Returns the exterior ring of the `Polygon` value *poly* as a `LineString`.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,1,1 1))';
mysql> SELECT AsText(ExteriorRing(GeomFromText(@poly)));
+-----+
| AsText(ExteriorRing(GeomFromText(@poly))) |
+-----+
```

```

+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0) |
+-----+

```

- `InteriorRingN(poly,N)`

Returns the *N*-th interior ring for the `Polygon` value *poly* as a `LineString`. Rings are numbered beginning with 1.

```

mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
+-----+
| AsText(InteriorRingN(GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1) |
+-----+

```

- `NumInteriorRings(poly)`

Returns the number of interior rings in the `Polygon` value *poly*.

```

mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT NumInteriorRings(GeomFromText(@poly));
+-----+
| NumInteriorRings(GeomFromText(@poly)) |
+-----+
| 1 |
+-----+

```

### 21.5.2.6. MultiPolygon Functions

These functions return properties of `MultiPolygon` values.

- `Area(mpoly)`

Returns as a double-precision number the area of the `MultiPolygon` value *mpoly*, as measured in its spatial reference system.

```

mysql> SET @mpoly =
-> 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT Area(GeomFromText(@mpoly));
+-----+
| Area(GeomFromText(@mpoly)) |
+-----+
| 8 |
+-----+

```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- `Centroid(mpoly)`

Returns the mathematical centroid for the `MultiPolygon` value *mpoly* as a `Point`. The result is not guaranteed to be on the `MultiPolygon`.

- `PointOnSurface(mpoly)`

Returns a `Point` value that is guaranteed to be on the `MultiPolygon` value *mpoly*.

### 21.5.2.7. GeometryCollection Functions

These functions return properties of `GeometryCollection` values.

- `GeometryN(gc,N)`

Returns the *N*-th geometry in the `GeometryCollection` value *gc*. Geometries are numbered beginning with 1.

```

mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT AsText(GeometryN(GeomFromText(@gc),1));
+-----+

```

```
| AsText(GeometryN(GeomFromText(@gc),1)) |
+-----+
| POINT(1 1) |
+-----+
```

- `NumGeometries(gc)`

Returns the number of geometries in the `GeometryCollection` value `gc`.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT NumGeometries(GeomFromText(@gc));
+-----+
| NumGeometries(GeomFromText(@gc)) |
+-----+
| 2 |
+-----+
```

## 21.5.3. Functions That Create New Geometries from Existing Ones

The following sections describe functions that take geometry values as arguments and return new geometry values.

### 21.5.3.1. Geometry Functions That Produce New Geometries

[Section 21.5.2, “Geometry Functions”](#), discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- `Envelope(g)`
- `StartPoint(ls)`
- `EndPoint(ls)`
- `PointN(ls,N)`
- `ExteriorRing(poly)`
- `InteriorRingN(poly,N)`
- `GeometryN(gc,N)`

### 21.5.3.2. Spatial Operators

OpenGIS proposes a number of other functions that can produce geometries. They are designed to implement spatial operators.

These functions are not implemented in MySQL. They may appear in future releases.

- `Buffer(g,d)`  
Returns a geometry that represents all points whose distance from the geometry value `g` is less than or equal to a distance of `d`.
- `ConvexHull(g)`  
Returns a geometry that represents the convex hull of the geometry value `g`.
- `Difference(g1,g2)`  
Returns a geometry that represents the point set difference of the geometry value `g1` with `g2`.
- `Intersection(g1,g2)`  
Returns a geometry that represents the point set intersection of the geometry values `g1` with `g2`.
- `SymDifference(g1,g2)`  
Returns a geometry that represents the point set symmetric difference of the geometry value `g1` with `g2`.
- `Union(g1,g2)`

Returns a geometry that represents the point set union of the geometry values *g1* and *g2*.

## 21.5.4. Functions for Testing Spatial Relations Between Geometric Objects

The functions described in these sections take two geometries as input parameters and return a qualitative or quantitative relation between them.

## 21.5.5. Relations on Geometry Minimal Bounding Rectangles (MBRs)

MySQL provides several functions that test relations between minimal bounding rectangles of two geometries *g1* and *g2*. The return values 1 and 0 indicate true and false, respectively.

- `MBRContains(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of *g1* contains the Minimum Bounding Rectangle of *g2*. This tests the opposite relationship as `MBRWithin()`.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRContains(@g2,@g1);
```

| MBRContains(@g1,@g2) | MBRContains(@g2,@g1) |
|----------------------|----------------------|
| 1                    | 0                    |

- `MBRDisjoint(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* are disjoint (do not intersect).

- `MBREqual(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* are the same.

- `MBRIntersects(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* intersect.

- `MBROverlaps(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* overlap. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

- `MBRTouches(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* touch. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

- `MBRWithin(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of *g1* is within the Minimum Bounding Rectangle of *g2*. This tests the opposite relationship as `MBRContains()`.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
```

| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
|--------------------|--------------------|
| 1                  | 0                  |

## 21.5.6. Functions That Test Spatial Relationships Between Geometries

The OpenGIS specification defines the following functions. They test the relationship between two geometry values *g1* and *g2*.

The return values 1 and 0 indicate true and false, respectively.

### Note

Currently, MySQL does not implement these functions according to the specification. Those that are implemented return the same result as the corresponding MBR-based functions. This includes functions in the following list other than `Distance()` and `Related()`.

These functions may be implemented in future releases with full support for spatial analysis, not just MBR-based support.

- `Contains(g1,g2)`  
Returns 1 or 0 to indicate whether `g1` completely contains `g2`. This tests the opposite relationship as `Within()`.
- `Crosses(g1,g2)`  
Returns 1 if `g1` spatially crosses `g2`. Returns `NULL` if `g1` is a `Polygon` or a `MultiPolygon`, or if `g2` is a `Point` or a `MultiPoint`. Otherwise, returns 0.  
  
The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:
  - The two geometries intersect
  - Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
  - Their intersection is not equal to either of the two given geometries
- `Disjoint(g1,g2)`  
Returns 1 or 0 to indicate whether `g1` is spatially disjoint from (does not intersect) `g2`.
- `Distance(g1,g2)`  
Returns as a double-precision number the shortest distance between any two points in the two geometries.
- `Equals(g1,g2)`  
Returns 1 or 0 to indicate whether `g1` is spatially equal to `g2`.
- `Intersects(g1,g2)`  
Returns 1 or 0 to indicate whether `g1` spatially intersects `g2`.
- `Overlaps(g1,g2)`  
Returns 1 or 0 to indicate whether `g1` spatially overlaps `g2`. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.
- `Related(g1,g2,pattern_matrix)`  
Returns 1 or 0 to indicate whether the spatial relationship specified by `pattern_matrix` exists between `g1` and `g2`. Returns -1 if the arguments are `NULL`. The pattern matrix is a string. Its specification will be noted here if this function is implemented.
- `Touches(g1,g2)`  
Returns 1 or 0 to indicate whether `g1` spatially touches `g2`. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.
- `Within(g1,g2)`  
Returns 1 or 0 to indicate whether `g1` is spatially within `g2`. This tests the opposite relationship as `Contains()`.

## 21.6. Optimizing Spatial Analysis

Search operations in non-spatial databases can be optimized using `SPATIAL` indexes. This is true for spatial databases as well. With the help of a great variety of multi-dimensional indexing methods that have previously been designed, it is possible to optimize spatial searches. The most typical of these are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for `SPATIAL` indexes on spatial columns. A `SPATIAL` index is built using the MBR of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-`SPATIAL` index, you must declare a prefix for any spatial column except for `POINT` columns.

`MyISAM` supports both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in [Section 12.1.7, “CREATE INDEX Syntax”](#).

## 21.6.1. Creating Spatial Indexes

MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but extended with the `SPATIAL` keyword. Currently, columns in spatial indexes must be declared `NOT NULL`. The following examples demonstrate how to create spatial indexes:

- With `CREATE TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
```

- With `ALTER TABLE`:

```
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With `CREATE INDEX`:

```
CREATE SPATIAL INDEX sp_index ON geom (g);
```

For `MyISAM` tables, `SPATIAL INDEX` creates an R-tree index. For storage engines that support non-spatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values will be useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see [Section 12.1.7, “CREATE INDEX Syntax”](#).

To drop spatial indexes, use `ALTER TABLE` or `DROP INDEX`:

- With `ALTER TABLE`:

```
ALTER TABLE geom DROP INDEX g;
```

- With `DROP INDEX`:

```
DROP INDEX sp_index ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| fid | int(11) | | PRI | NULL | auto_increment |
| g | geometry | | | | |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT COUNT(*) FROM geom;
+-----+
| count(*) |
+-----+
| 32376 |
+-----+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376 Duplicates: 0 Warnings: 0
```

## 21.6.2. Using a Spatial Index

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
 31000 15000,
 31000 16000,
 30000 16000,
 30000 15000))';
mysql> SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g);
```

| fid | AsText(g)                                                     |
|-----|---------------------------------------------------------------|
| 21  | LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30 ... |
| 22  | LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8, ... |
| 23  | LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4, ... |
| 24  | LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4, ... |
| 25  | LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882. ... |
| 26  | LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4, ... |
| 249 | LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946. ... |
| 1   | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ... |
| 2   | LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136. ... |
| 3   | LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ... |
| 4   | LINESTRING(30155.2 15121.4,30140.4 15118.6,30142 15109,30 ... |
| 5   | LINESTRING(30192.4 15085,30177.6 15082.2,30179.2 15072.4, ... |
| 6   | LINESTRING(30244 15087,30229 15086.2,30229.4 15076.4,3024 ... |
| 7   | LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ... |
| 10  | LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ... |
| 11  | LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ... |
| 13  | LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053,3011 ... |
| 154 | LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ... |
| 155 | LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ... |
| 157 | LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ... |

20 rows in set (0.00 sec)

Use `EXPLAIN` to check the way this query is executed:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
 31000 15000,
 31000 16000,
 30000 16000,
 30000 15000))';
mysql> EXPLAIN SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: geom
 type: range
possible_keys: g
 key: g
 key_len: 32
 ref: NULL
 rows: 50
 Extra: Using where
1 row in set (0.00 sec)
```

Check what would happen without a spatial index:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
 31000 15000,
 31000 16000,
 30000 16000,
 30000 15000))';
mysql> EXPLAIN SELECT fid,AsText(g) FROM g IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: geom
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
```

```

rows: 32376
Extra: Using where
1 row in set (0.00 sec)

```

Executing the `SELECT` statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
 31000 15000,
 31000 16000,
 30000 16000,
 30000 15000))';
mysql> SELECT fid,AsText(g) FROM geom IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g);
+-----+-----+
| fid | AsText(g) |
+-----+-----+
1	LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ...
2	LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136. ...
3	LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ...
4	LINESTRING(30155.2 15121.4,30140.4 15118.6,30142 15109,30 ...
5	LINESTRING(30192.4 15085,30177.6 15082.2,30179.2 15072.4, ...
6	LINESTRING(30244 15087,30229 15086.2,30229.4 15076.4,3024 ...
7	LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ...

21	LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30 ...
22	LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8, ...
23	LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4, ...
24	LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4, ...
25	LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882. ...
26	LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4, ...
154	LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ...
155	LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ...
157	LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ...
249	LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946. ...
+-----+-----+
20 rows in set (0.46 sec)

```

In future releases, spatial indexes may also be used for optimizing other functions. See [Section 21.5.4, “Functions for Testing Spatial Relations Between Geometric Objects”](#).

## 21.7. MySQL Conformance and Compatibility

MySQL does not yet implement the following GIS features:

- Additional Metadata Views

OpenGIS specifications propose several additional metadata views. For example, a system view named `GEOMETRY_COLUMNS` contains a description of geometry columns, one row for each geometry column in the database.

- The OpenGIS function `Length()` on `LineString` and `MultiLineString` currently should be called in MySQL as `GLength()`

The problem is that there is an existing SQL function `Length()` that calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context. We need either to solve this somehow, or decide on another function name.

---

## Chapter 22. Stored Procedures and Functions

Stored routines (procedures and functions) are supported in MySQL 5.1. A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored procedure instead.

Answers to some questions that are commonly asked regarding stored routines in MySQL can be found in [Section A.4, “MySQL 5.1 FAQ — Stored Procedures”](#).

### MySQL Enterprise

For expert advice on using stored procedures and functions subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

Some situations where stored routines can be particularly useful:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also allow you to have libraries of functions in the database server. This is a feature shared by modern application languages that allow such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2.

The MySQL implementation of stored routines is still in progress. All syntax described in this chapter is supported and any limitations and extensions are documented where appropriate. Further discussion of restrictions on use of stored routines is given in [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

Binary logging for stored routines takes place as described in [Section 22.4, “Binary Logging of Stored Routines and Triggers”](#).

Recursive stored procedures are disabled by default, but can be enabled on the server by setting the `max_sp_recursion_depth` server system variable to a nonzero value. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See [Section 5.1.3, “System Variables”](#), for more information.

Stored functions cannot be recursive. See [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

### 22.1. Stored Routines and the Grant Tables

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped when the routine creator drops the routine.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped when the creator drops the routine). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted and dropped.

## 22.2. Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with `CREATE PROCEDURE` and `CREATE FUNCTION` statements. A procedure is invoked using a `CALL` statement, and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. Stored routines may call other stored routines.

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are disallowed.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

MySQL supports the very useful extension that allows the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See [Section 28.2.3.52](#), “`mysql_real_connect()`”, and [Section 28.2.9](#), “C API Handling of Multiple Statement Execution”.

### MySQL Enterprise

MySQL Enterprise subscribers will find numerous articles about stored routines in the MySQL Enterprise Knowledge Base. Access to this collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

The following sections describe the syntax used to create, alter, drop, and invoke stored procedures and functions.

### 22.2.1. CREATE PROCEDURE and CREATE FUNCTION Syntax

```
CREATE
 [DEFINER = { user | CURRENT_USER }]
 PROCEDURE sp_name ([proc_parameter[,...]])
 [characteristic ...] routine_body

CREATE
 [DEFINER = { user | CURRENT_USER }]
 FUNCTION sp_name ([func_parameter[,...]])
 RETURNS type
 [characteristic ...] routine_body

proc_parameter:
 [IN | OUT | INOUT] param_name type

func_parameter:
 param_name type

type:
 Any valid MySQL data type

characteristic:
 LANGUAGE SQL
 [NOT] DETERMINISTIC
 { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
 SQL SECURITY { DEFINER | INVOKER }
 COMMENT 'string'

routine_body:
 Valid SQL procedure statement
```

These statements create stored routines. By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

To execute these statements, it is necessary to have the `CREATE ROUTINE` privilege. If binary logging is enabled, the `CREATE FUNCTION` statement might also require the `SUPER` privilege, as described in [Section 22.4](#), “Binary Logging of Stored Routines”.

and Triggers”. MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator.

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described later.

If the routine name is the same as the name of a built-in SQL function, you must use a space between the name and the following parenthesis when defining the routine, or a syntax error occurs. This is also true when you invoke the routine later. For this reason, we suggest that it is better to avoid re-using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always allowable to have spaces after a routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used.

Each parameter can be declared to use any valid data type, except that the `COLLATE` attribute cannot be used.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

### Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. (`FUNCTION` parameters are always regarded as `IN` parameters.)

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable so that you can obtain its value when the procedure returns. (For an example, see [Section 22.2.4, “CALL Statement Syntax”](#).) If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The `routine_body` consists of a valid SQL procedure statement. This can be a simple statement such as `SELECT` or `INSERT`, or it can be a compound statement written using `BEGIN` and `END`. Compound statement syntax is described in [Section 22.2.5, “BEGIN . . . END Compound Statement Syntax”](#). Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described later in this chapter. See, for example, [Section 22.2.6, “DECLARE Statement Syntax”](#), and [Section 22.2.10, “Flow Control Constructs”](#).

Some statements are not allowed in stored routines; see [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

MySQL stores the `sql_mode` system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force, *regardless of the current server SQL mode*.

The `CREATE FUNCTION` statement was used in earlier versions of MySQL to support UDFs (user-defined functions). See [Section 31.3, “Adding New Functions to MySQL”](#). UDFs continue to be supported, even with the existence of stored functions. A UDF can be regarded as an external stored function. However, do note that stored functions share their namespace with UDFs. See [Section 8.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

A procedure or function is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`.

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is non-deterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is invoked only once within a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

In versions prior to 5.1.21-beta, the `DETERMINISTIC` characteristic is accepted, but not used by the optimizer. However, if binary logging is enabled, this characteristic always affects which routine definitions MySQL accepts. See [Section 22.4, “Binary Logging of Stored Routines and Triggers”](#).

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advis-

ory only. The server does not use them to constrain what kinds of statements a routine will be allowed to execute.

- `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.
- `NO SQL` indicates that the routine contains no SQL statements.
- `READS SQL DATA` indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.
- `MODIFIES SQL DATA` indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The `SQL SECURITY` characteristic can be used to specify whether the routine should be executed using the permissions of the user who creates the routine or the user who invokes it. The default value is `DEFINER`. This feature is new in SQL:2003. The creator or invoker must have permission to access the database with which the routine is associated. It is necessary to have the `EXECUTE` privilege to be able to execute the routine. The user that must have this privilege is either the definer or invoker, depending on how the `SQL SECURITY` characteristic is set.

The optional `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic. The `DEFINER` clause was added in MySQL 5.1.8.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account in '`user_name`'@'`host_name`' format (the same format used in the `GRANT` statement). The `user_name` and `host_name` values both are required. The definer can also be given as `CURRENT_USER` or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. (This is the same as `DEFINER = CURRENT_USER`.)

If you specify the `DEFINER` clause, these rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

Although it is possible to create routines with a non-existent `DEFINER` value, an error occurs if the routine executes with definer privileges but the definer does not exist at execution time.

When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are disallowed.

The server uses the data type of a routine parameter or function return value as follows. These rules also apply to local routine variables created with the `DECLARE` statement (Section 22.2.7.1, “`DECLARE Local Variables`”).

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict mode.
- Only scalar values can be assigned to parameters or variables. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.
- For character data types, if there is a `CHARACTER SET` clause in the declaration, the specified character set and its default collation are used. If there is no such clause, the database character set and collation that are in effect at the time the routine is created are used. (These are given by the values of the `character_set_database` and `collation_database` system variables.) The `COLLATE` attribute is not supported. (This includes use of `BINARY`, because in this context `BINARY` specifies the binary collation of the character set.)

The `COMMENT` clause is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

MySQL allows routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also allows stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that do explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to allow them.

Statements that return a result set cannot be used within a stored function. This includes `SELECT` statements that do not use `INTO` to fetch column values into variables, `SHOW` statements, and other statements such as `EXPLAIN`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

The following is an example of a simple stored procedure that uses an `OUT` parameter. The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This allows the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
-> SELECT COUNT(*) INTO param1 FROM t;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
+-----+
| @a |
+-----+
| 3 |
+-----+
1 row in set (0.00 sec)
```

When using the `delimiter` command, you should avoid the use of the backslash (“\”) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world! |
+-----+
1 row in set (0.00 sec)
```

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see [Section 22.2.4, “CALL Statement Syntax”](#).

## 22.2.2. ALTER PROCEDURE and ALTER FUNCTION Syntax

```
ALTER {PROCEDURE | FUNCTION} sp_name [characteristic ...]

characteristic:
{ CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
SQL SECURITY { DEFINER | INVOKER }
COMMENT 'string'
```

This statement can be used to change the characteristics of a stored procedure or function. You must have the `ALTER ROUTINE` privilege for the routine. (That privilege is granted automatically to the routine creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in [Section 22.4, “Binary Logging of Stored Routines and Triggers”](#).

More than one change may be specified in an `ALTER PROCEDURE` or `ALTER FUNCTION` statement.

## 22.2.3. DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the `ALTER ROUTINE` privilege for the routine. (That privilege is granted automatically to the routine creator.)

The `IF EXISTS` clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with `SHOW WARNINGS`.

`DROP FUNCTION` is also used to drop user-defined functions (see [Section 31.3.3, “DROP FUNCTION Syntax”](#)).

## 22.2.4. CALL Statement Syntax

```
CALL sp_name([parameter[,...]])
CALL sp_name[()]
```

The `CALL` statement invokes a procedure that was defined previously with `CREATE PROCEDURE`.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. It also “returns” the number of rows affected, which a client program can obtain at the SQL level by calling the `ROW_COUNT()` function and from C by calling the `mysql_affected_rows()` C API function.

As of MySQL 5.1.13, stored procedures that take no arguments can be invoked without parentheses. That is, `CALL p()` and `CALL p` are equivalent.

To get back a value from a procedure using an `OUT` or `INOUT` parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.) For an `INOUT` parameter, initialize its value before passing it to the procedure. The following procedure has an `OUT` parameter that the procedure sets to the current server version, and an `INOUT` value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
 # Set value of OUT parameter
 SELECT VERSION() INTO ver_param;
 # Increment value of INOUT parameter
 SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the `INOUT` parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.1.12-beta-log | 11 |
+-----+-----+
```

If you write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, you *must* set the `CLIENT_MULTI_RESULTS` flag, either explicitly, or implicitly by setting `CLIENT_MULTI_STATEMENTS` when you call `mysql_real_connect()`. This is because each such stored procedure produces multiple results: the result sets returned by statements executed within the procedure, as well as a result to indicate the call status. To process the result of a `CALL` statement, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 28.2.9, “C API Handling of Multiple Statement Execution”](#).

For programs written in a language that provides a MySQL interface, there is no native method for directly retrieving the results of `OUT` or `INOUT` parameters from `CALL` statements. To get the parameter values, pass user-defined variables to the procedure in the `CALL` statement and then execute a `SELECT` statement to produce a result set containing the variable values. The following example illustrates the technique (without error checking) for a stored procedure `p1` that has two `OUT` parameters.

```
mysql_query(mysql, "CALL p1(@param1, @param2)");
mysql_query(mysql, "SELECT @param1, @param2");
result = mysql_store_result(mysql);
row = mysql_fetch_row(result);
mysql_free_result(result);
```

After the preceding code executes, `row[0]` and `row[1]` contain the values of `@param1` and `@param2`, respectively.

To handle `INOUT` parameters, execute a statement prior to the `CALL` that sets the user variables to the values to be passed to the procedure.

## 22.2.5. BEGIN ... END Compound Statement Syntax

```
[begin_label:] BEGIN
 [statement_list]
END [end_label]
```

`BEGIN ... END` syntax is used for writing compound statements, which can appear within stored routines and triggers. A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. `statement_list` represents a list of one or more statements. Each statement within `statement_list` must be terminated by a semicolon (`;`) statement delimiter. Note that `statement_list` is optional, which means that the empty compound statement (`BEGIN END`) is legal.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. This is handled in the `mysql` command-line client with the `delimiter` command. Changing the `;` end-of-statement delimiter (for example, to `//`) allows `;` to be used in a routine body. For an example, see [Section 22.2.1, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

A compound statement can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

The optional `[NOT] ATOMIC` clause is not yet supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

## 22.2.6. DECLARE Statement Syntax

The `DECLARE` statement is used to define various items local to a routine:

- Local variables. See [Section 22.2.7, “Variables in Stored Routines”](#).
- Conditions and handlers. See [Section 22.2.8, “Conditions and Handlers”](#).
- Cursors. See [Section 22.2.9, “Cursors”](#).

The `SIGNAL` and `RESIGNAL` statements are not currently supported.

`DECLARE` is allowed only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

## 22.2.7. Variables in Stored Routines

You may declare and use variables within a routine.

### 22.2.7.1. DECLARE Local Variables

```
DECLARE var_name[,...] type [DEFAULT value]
```

This statement is used to declare local variables. To provide a default value for the variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like routine parameters with respect to data type and overflow checking. See [Section 22.2.1, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

The scope of a local variable is within the `BEGIN ... END` block where it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

### 22.2.7.2. Variable SET Statement

```
SET var_name = expr [, var_name = expr] ...
```

The `SET` statement in stored routines is an extended version of the general `SET` statement. Referenced variables may be ones declared inside a routine, or global system variables.

The `SET` statement in stored routines is implemented as part of the pre-existing `SET` syntax. This allows an extended syntax of `SET a=x, b=y, ...` where different variable types (locally declared variables and global and session server variables) can be mixed. This also allows combinations of local variables and some options that make sense only for system variables; in that case, the options are recognized but ignored.

### 22.2.7.3. SELECT ... INTO Statement

```
SELECT col_name[,...] INTO var_name[,...] table_expr
```

This `SELECT` syntax stores selected columns directly into variables. Therefore, only a single row may be retrieved.

```
SELECT id,data INTO x,y FROM test.t1 LIMIT 1;
```

User variable names are not case sensitive. See [Section 8.4, “User-Defined Variables”](#).

### Important

SQL variable names should not be the same as column names. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. For example, in the following statement, `xname` is interpreted as a reference to the `xname` variable rather than the `xname` column:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
 DECLARE xname VARCHAR(5) DEFAULT 'bob';
 DECLARE newname VARCHAR(5);
 DECLARE xid INT;

 SELECT xname,id INTO newname,xid
 FROM table1 WHERE xname = xname;
 SELECT newname;
END;
```

When this procedure is called, the `newname` variable returns the value `'bob'` regardless of the value of the `table1.xname` column.

See also [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

## 22.2.8. Conditions and Handlers

Certain conditions may require specific handling. These conditions can relate to errors, as well as to general flow control inside a routine.

### 22.2.8.1. DECLARE Conditions

```
DECLARE condition_name CONDITION FOR condition_value
condition_value:
 SQLSTATE [VALUE] sqlstate_value
 | mysql_error_code
```

This statement specifies conditions that need specific handling. It associates a name with a specified error condition. The name can subsequently be used in a `DECLARE HANDLER` statement. See [Section 22.2.8.2, “DECLARE Handlers”](#).

A `condition_value` can be an SQLSTATE value or a MySQL error code. For a list of SQLSTATE and error values, see [Section B.2, “Server Error Codes and Messages”](#).

### 22.2.8.2. DECLARE Handlers

```
DECLARE handler_type HANDLER FOR condition_value[...] statement
handler_type:
 CONTINUE
 EXIT
 | UNDO
condition_value:
 SQLSTATE [VALUE] sqlstate_value
 condition_name
 SQLWARNING
 NOT FOUND
 SQLEXCEPTION
 | mysql_error_code
```

The `DECLARE ... HANDLER` statement specifies handlers that each may deal with one or more conditions. If one of these conditions occurs, the specified `statement` is executed. `statement` can be a simple statement (for example, `SET var_name = value`), or it can be a compound statement written using `BEGIN` and `END` (see [Section 22.2.5, “BEGIN ... END Compound Statement Syntax”](#)).

For a `CONTINUE` handler, execution of the current routine continues after execution of the handler statement. For an `EXIT` handler, execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. (This is true even if the condition occurs in an inner block.) The `UNDO` handler type statement is not yet supported.

If a condition occurs for which no handler has been declared, the default action is `EXIT`.

A *condition\_value* can be any of the following values:

- An SQLSTATE value or a MySQL error code. You should not use SQLSTATE value '00000' or error code 0, because those indicate success rather than an error condition. For a list of SQLSTATE and error values, see [Section B.2, “Server Error Codes and Messages”](#).
- A condition name previously specified with `DECLARE ... CONDITION`. See [Section 22.2.8.1, “DECLARE Conditions”](#).
- `SQLWARNING` is shorthand for all SQLSTATE codes that begin with 01.
- `NOT FOUND` is shorthand for all SQLSTATE codes that begin with 02. This is relevant only within the context of cursors and is used to control what happens when a cursor reaches the end of a data set.
- `SQLEXCEPTION` is shorthand for all SQLSTATE codes not caught by `SQLWARNING` or `NOT FOUND`.

Example:

```
mysql> CREATE TABLE test.t (s1 int,primary key (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
-> DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
-> SET @x = 1;
-> INSERT INTO test.t VALUES (1);
-> SET @x = 2;
-> INSERT INTO test.t VALUES (1);
-> SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo();//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x |
+-----+
| 3 |
+-----+
1 row in set (0.00 sec)
```

The example associates a handler with SQLSTATE 23000, which occurs for a duplicate-key error. Notice that @x is 3, which shows that MySQL executed to the end of the procedure. If the line `DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;` had not been present, MySQL would have taken the default path (`EXIT`) after the second `INSERT` failed due to the `PRIMARY KEY` constraint, and `SELECT @x` would have returned 2.

If you want to ignore a condition, you can declare a `CONTINUE` handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The statement associated with a handler cannot use `ITERATE` or `LEAVE` to refer to labels for blocks that enclose the handler declaration. That is, the scope of a block label does not include the code for handlers declared within the block. Consider the following example, where the `REPEAT` block has a label of `retry`:

```
CREATE PROCEDURE p ()
BEGIN
 DECLARE i INT DEFAULT 3;
 retry:
 REPEAT
 BEGIN
 DECLARE CONTINUE HANDLER FOR SQLWARNING
 BEGIN
 ITERATE retry; # illegal
 END;
 END;
 IF i < 0 THEN
 LEAVE retry; # legal
 END IF;
 SET i = i - 1;
 UNTIL FALSE END REPEAT;
END;
```

The label is in scope for the `IF` statement within the block. It is not in scope for the `CONTINUE` handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid using references to outer labels in handlers, you can use different strategies:

- If you want to leave the block, you can use an [EXIT](#) handler:

```
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

- If you want to iterate, you can set a status variable in the handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

```
CREATE PROCEDURE p ()
BEGIN
 DECLARE i INT DEFAULT 3;
 DECLARE done INT DEFAULT FALSE;
 retry:
 REPEAT
 BEGIN
 DECLARE CONTINUE HANDLER FOR SQLWARNING
 BEGIN
 SET done = TRUE;
 END;
 END;
 IF NOT done AND i < 0 THEN
 LEAVE retry;
 END IF;
 SET i = i - 1;
 UNTIL FALSE END REPEAT;
END;
```

## 22.2.9. Cursors

Cursors are supported inside stored procedures and functions and triggers. The syntax is as in embedded SQL. Cursors currently have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable
- Non-scrollable: Can be traversed only in one direction and cannot skip rows

Cursors must be declared before declaring handlers. Variables and conditions must be declared before declaring either cursors or handlers.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
 DECLARE done INT DEFAULT 0;
 DECLARE a CHAR(16);
 DECLARE b,c INT;
 DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
 DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
 DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

 OPEN cur1;
 OPEN cur2;

 REPEAT
 FETCH cur1 INTO a, b;
 FETCH cur2 INTO c;
 IF NOT done THEN
 IF b < c THEN
 INSERT INTO test.t3 VALUES (a,b);
 ELSE
 INSERT INTO test.t3 VALUES (a,c);
 END IF;
 END IF;
 UNTIL done END REPEAT;

 CLOSE cur1;
 CLOSE cur2;
END
```

### 22.2.9.1. Declaring Cursors

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor. Multiple cursors may be declared in a routine, but each cursor in a given block must have a unique name.

The `SELECT` statement cannot have an `INTO` clause.

### 22.2.9.2. Cursor `OPEN` Statement

```
OPEN cursor_name
```

This statement opens a previously declared cursor.

### 22.2.9.3. Cursor `FETCH` Statement

```
FETCH cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row (if a row exists) using the specified open cursor, and advances the cursor pointer.

If no more rows are available, a No Data condition occurs with SQLSTATE value 02000. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). An example is shown in [Section 22.2.9, “Cursors”](#).

### 22.2.9.4. Cursor `CLOSE` Statement

```
CLOSE cursor_name
```

This statement closes a previously opened cursor.

If not closed explicitly, a cursor is closed at the end of the compound statement in which it was declared.

## 22.2.10. Flow Control Constructs

The `IF`, `CASE`, `ITERATE`, `LEAVE LOOP`, `WHILE`, and `REPEAT` constructs are fully implemented.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an `IF` statement might contain a `WHILE` loop, which itself contains a `CASE` statement.

`FOR` loops are not currently supported.

### 22.2.10.1. `IF` Statement

```
IF search_condition THEN statement_list
 [ELSEIF search_condition THEN statement_list] ...
 [ELSE statement_list]
END IF
```

`IF` implements a basic conditional construct. If the *search\_condition* evaluates to true, the corresponding SQL statement list is executed. If no *search\_condition* matches, the statement list in the `ELSE` clause is executed. Each *statement\_list* consists of one or more statements.

#### Note

There is also an `IF()` function, which differs from the `IF` statement described here. See [Section 11.3, “Control Flow Functions”](#).

An `IF ... END IF` block — like all other flow-control blocks used within stored routines — must be terminated with a semi-colon, as shown in this example:

```
DELIMITER //
CREATE FUNCTION SimpleCompare(n INT, m INT)
 RETURNS VARCHAR(20)
BEGIN
 DECLARE s VARCHAR(20);
 IF n > m THEN SET s = '>';
 ELSEIF n = m THEN SET s = '=';
 ELSE SET s = '<';
 END IF;
 SET s = CONCAT(n, ' ', s, ' ', m);
END IF;
```

```

RETURN s;
END //
DELIMITER ;

```

As with other flow-control constructs, `IF ... END IF` blocks may be nested within other flow-control constructs, including other `IF` statements. Each `IF` must be terminated by its own `END IF` followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

```

DELIMITER //
CREATE FUNCTION VerboseCompare (n INT, m INT)
RETURNS VARCHAR(50)
BEGIN
 DECLARE s VARCHAR(50);
 IF n = m THEN SET s = 'equals';
 ELSE
 IF n > m THEN SET s = 'greater';
 ELSE SET s = 'less';
 END IF;
 SET s = CONCAT('is ', s, ' than');
 END IF;
 SET s = CONCAT(n, ' ', s, ' ', m, '.');
 RETURN s;
END //
DELIMITER ;

```

In this example, the inner `IF` is evaluated only if `n` is not equal to `m`.

### 22.2.10.2. CASE Statement

```

CASE case_value
 WHEN when_value THEN statement_list
 [WHEN when_value THEN statement_list] ...
 [ELSE statement_list]
END CASE

```

Or:

```

CASE
 WHEN search_condition THEN statement_list
 [WHEN search_condition THEN statement_list] ...
 [ELSE statement_list]
END CASE

```

The `CASE` statement for stored routines implements a complex conditional construct. If a `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the `ELSE` clause is executed. Each `statement_list` consists of one or more statements.

#### Note

If no search condition matches the value tested, and the `CASE` statement contains no `ELSE` clause, a `CASE NOT FOUND FOR CASE STATEMENT` error results.

Each `statement_list` consists of one or more statements; an empty `statement_list` is not allowed. To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty `BEGIN ... END` block, as shown in this example:

```

DELIMITER |
CREATE PROCEDURE p()
BEGIN
 DECLARE v INT DEFAULT 1;
 CASE v
 WHEN 2 THEN SELECT v;
 WHEN 3 THEN SELECT 0;
 ELSE
 BEGIN
 END;
 END CASE;
END;
|

```

(The indentation used here in the `ELSE` clause is for purposes of clarity only, and is not otherwise significant.)

The syntax of the `CASE` statement used inside stored routines differs slightly from that of the SQL `CASE` expression described in Section 11.3, “Control Flow Functions”. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

### 22.2.10.3. LOOP Statement

```
[begin_label:] LOOP
 statement_list
END LOOP [end_label]
```

`LOOP` implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements. The statements within the loop are repeated until the loop is exited; usually this is accomplished with a `LEAVE` statement.

A `LOOP` statement can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

### 22.2.10.4. LEAVE Statement

```
LEAVE label
```

This statement is used to exit any labeled flow control construct. It can be used within `BEGIN . . . END` or loop constructs (`LOOP`, `REPEAT`, `WHILE`).

### 22.2.10.5. ITERATE Statement

```
ITERATE label
```

`ITERATE` can appear only within `LOOP`, `REPEAT`, and `WHILE` statements. `ITERATE` means “do the loop again.”

Example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
 label1: LOOP
 SET p1 = p1 + 1;
 IF p1 < 10 THEN ITERATE label1; END IF;
 LEAVE label1;
 END LOOP label1;
 SET @x = p1;
END
```

### 22.2.10.6. REPEAT Statement

```
[begin_label:] REPEAT
 statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a `REPEAT` statement is repeated until the `search_condition` is true. Thus, a `REPEAT` always enters the loop at least once. `statement_list` consists of one or more statements.

A `REPEAT` statement can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

Example:

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
-> SET @x = 0;
-> REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x |
+-----+
| 1001 |
+-----+
1 row in set (0.00 sec)
```

### 22.2.10.7. WHILE Statement

```
[begin_label:] WHILE search_condition DO
 statement_list
END WHILE [end_label]
```

The statement list within a **WHILE** statement is repeated as long as the *search\_condition* is true. *statement\_list* consists of one or more statements.

A **WHILE** statement can be labeled. *end\_label* cannot be given unless *begin\_label* also is present. If both are present, they must be the same.

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
 DECLARE v1 INT DEFAULT 5;

 WHILE v1 > 0 DO
 ...
 SET v1 = v1 - 1;
 END WHILE;
END
```

### 22.2.11. RETURN Statement Syntax

```
RETURN expr
```

The **RETURN** statement terminates execution of a stored function and returns the value *expr* to the function caller. There must be at least one **RETURN** statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events.

## 22.3. Stored Procedures, Functions, Triggers, and LAST\_INSERT\_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of **LAST\_INSERT\_ID()** changes the same way as for statements executed outside the body of these kinds of objects (see [Section 11.11.3, “Information Functions”](#)). The effect of a stored routine or trigger upon the value of **LAST\_INSERT\_ID()** that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of **LAST\_INSERT\_ID()**, the changed value will be seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

## 22.4. Binary Logging of Stored Routines and Triggers

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 18.4, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 6.2.2, “Using Backups for Recovery”](#).

However, there are certain binary logging issues that apply with respect to stored routines (procedures and functions) and triggers, if logging occurs at the statement level:

- In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.

- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.
- If a routine that modifies data is non-deterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL 5.1 handles binary logging for stored routines and triggers. It states the current conditions that the implementation places on the use of stored routines, and what you can do to avoid problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the routine or trigger invocation. For general information about row-based logging, see [Section 18.1.2, “Replication Formats”](#).

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See [Section 5.2.4, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.1 can be summarized as follows. These conditions do not apply to stored procedures and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required.
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
 RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
 RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
 UPDATE t SET modtime = NOW() WHERE id = p_id;
 RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce non-deterministic results.

- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply and `SUPER` is not required for function creation.

For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see [Section 18.3.1, “Replication Features and Issues”](#).

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is non-deterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents non-replication of data changes that result from use of stored functions in non-logged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
 IF (a < 3) THEN
 INSERT INTO t2 VALUES (a);
 END IF;
 RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

Note: Before MySQL 5.1.7, you will see these `SELECT func_name()` statements logged as `DO func_name()`. The change to `SELECT` was made because use of `DO` was found to yield insufficient control over error code checking.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
  - It is possible for a function to follow different execution paths on master and slave servers.
  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
-> BEGIN
-> IF @@server_id=2 THEN dangerous_statement; END IF;
-> RETURN 1;
-> END;
-> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply and `SUPER` is not required for function creation.

- If a function that performs updates is non-deterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
  - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in non-procedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
| 14 |
+-----+
```

`NAME_CONST()` allows a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where `value` is the value of `@my_var` on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
  - Updates to transactional tables are not logged.
  - Updates to non-transactional tables are logged because rollback does not cancel them.
  - Updates to a mix of transactional and non-transactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

---

## Chapter 23. Triggers

A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table. For example, the following statements create a table and an `INSERT` trigger. The trigger sums the values inserted into one of the table's columns:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

### Important

MySQL triggers are activated by SQL statements *only*. They are not activated by changes in tables made by APIs that do not transmit SQL statements to the MySQL Server; in particular, they are not activated by updates made using the `NDB` API.

This chapter describes the syntax for creating and dropping triggers, and shows some examples of how to use them. Discussion of restrictions on use of triggers is given in [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#). Remarks regarding binary logging as it applies to triggers are given in [Section 22.4, “Binary Logging of Stored Routines and Triggers”](#).

For answers to some common questions about triggers in MySQL 5.1, see [Section A.5, “MySQL 5.1 FAQ — Triggers”](#).

### 23.1. CREATE TRIGGER Syntax

```
CREATE
[DEFINER = { user | CURRENT_USER }]
TRIGGER trigger_name trigger_time trigger_event
ON tbl_name FOR EACH ROW trigger_stmt
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

#### MySQL Enterprise

For expert advice on creating triggers subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

`CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger. (Before MySQL 5.1.6, this statement requires the `SUPER` privilege.)

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time.

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

`trigger_event` indicates the kind of statement that activates the trigger. The `trigger_event` can be one of the following:

- `INSERT`: The trigger is activated whenever a new row is inserted into the table; for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements.
- `UPDATE`: The trigger is activated whenever a row is modified; for example, through `UPDATE` statements.
- `DELETE`: The trigger is activated whenever a row is deleted from the table; for example, through `DELETE` and `REPLACE` statements. However, `DROP TABLE` and `TRUNCATE` statements on the table do *not* activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either. See [Section 12.2.9, “TRUNCATE Syntax”](#).

It is important to understand that the `trigger_event` does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger is activated by not only `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger will activate for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

There cannot be two triggers for a given table that have the same trigger action time and event. For example, you cannot have two

`BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

`trigger_stmt` is the statement to execute when the trigger activates. If you want to execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are allowable within stored routines. See [Section 22.2.5, “BEGIN ... END Compound Statement Syntax”](#). Some statements are not allowed in triggers; see [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

MySQL stores the `sql_mode` system variable setting that is in effect at the time a trigger is created, and always executes the trigger with this setting in force, *regardless of the current server SQL mode*.

### Note

Currently, triggers are not activated by cascaded foreign key actions. This limitation will be lifted as soon as possible.

In MySQL 5.1, you can write triggers containing direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
 a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 b4 INT DEFAULT 0
);

DELIMITER |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW BEGIN
 INSERT INTO test2 SET a2 = NEW.a1;
 DELETE FROM test3 WHERE a3 = NEW.a1;
 UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;

DELIMITER ;

INSERT INTO test3 (a3) VALUES
(NULL), (NULL), (NULL), (NULL), (NULL),
(NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
(0), (0), (0), (0), (0), (0), (0), (0), (0), (0);
```

Suppose that you insert the following values into table `test1` as shown here:

```
mysql> INSERT INTO test1 VALUES
-> (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8 Duplicates: 0 Warnings: 0
```

As a result, the data in the four tables will be as follows:

```
mysql> SELECT * FROM test1;
+-----+
| a1 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+-----+
| a2 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+-----+
| a3 |
```

```

+----+
| 2 |
| 5 |
| 6 |
| 9 |
| 10 |
+----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM test4;
+----+----+
| a4 | b4 |
+----+----+
1	3
2	0
3	1
4	2
5	0
6	0
7	1
8	1
9	0
10	0
+----+----+
10 rows in set (0.00 sec)

```

You can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account in `'user_name'@'host_name'` format (the same format used in the `GRANT` statement). The `user_name` and `host_name` values both are required. The definer can also be given as `CURRENT_USER` or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. (This is the same as `DEFINER = CURRENT_USER`.)

If you specify the `DEFINER` clause, these rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

Although it is possible to create triggers with a non-existent `DEFINER` value, it is not a good idea for such triggers to be activated until the definer actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

Note: Prior to MySQL 5.1.6, MySQL requires the `SUPER` privilege for the use of `CREATE TRIGGER`, so only the second of the preceding rules applies. As of 5.1.6, `CREATE TRIGGER` requires the `TRIGGER` privilege and `SUPER` is required only to be able to set `DEFINER` to a value other than your own account.

MySQL checks trigger privileges like this:

- At `CREATE TRIGGER` time, the user that issues the statement must have the `TRIGGER` privilege. (`SUPER` prior to MySQL 5.1.6.)
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
  - The `TRIGGER` privilege. (`SUPER` prior to MySQL 5.1.6.)
  - The `SELECT` privilege for the subject table if references to table columns occur via `OLD.col_name` or `NEW.col_name` in the trigger definition.
  - The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger definition.
  - Whatever other privileges normally are required for the statements executed by the trigger.

## 23.2. DROP TRIGGER Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the

default schema. `DROP TRIGGER` was added in MySQL 5.0.2. Its use requires the `TRIGGER` privilege for the table associated with the trigger. (This statement requires the `SUPER` privilege prior to MySQL 5.1.6.)

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a non-existent trigger when using `IF EXISTS`. See [Section 12.5.4.32, “SHOW WARNINGS Syntax”](#). The `IF EXISTS` clause was added in MySQL 5.1.14.

Triggers for a table are also dropped if you drop the table.

### Note

When upgrading from a version of MySQL older than MySQL 5.0.10 to 5.0.10 or newer — including all MySQL 5.1 releases — you must drop all triggers *before upgrading* and re-create them afterward, or else `DROP TRIGGER` does not work after the upgrade. See [Section 2.11.1, “Upgrading from MySQL 5.0 to 5.1”](#), for a suggested upgrade procedure.

## 23.3. Using Triggers

This section discusses how to use triggers in MySQL 5.1 and some limitations regarding their use. Additional information about trigger limitations is given in [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is associated with a table and is defined to activate when an `INSERT`, `DELETE`, or `UPDATE` statement for the table executes. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is deleted from a table or after each row that is updated.

### Important

MySQL triggers are activated by SQL statements *only*. They are not activated by changes in tables made by APIs that do not transmit SQL statements to the MySQL Server; in particular, they are not activated by updates made using the `NDB` API.

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement. The syntax for these statements is described in [Section 23.1, “CREATE TRIGGER Syntax”](#), and [Section 23.2, “DROP TRIGGER Syntax”](#).

Here is a simple example that associates a trigger with a table for `INSERT` statements. It acts as an accumulator to sum the values inserted into one of the columns of the table.

The following statements create a table and a trigger for it:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other allowable keyword here is `AFTER`.
- The keyword `INSERT` indicates the event that activates the trigger. In the example, `INSERT` statements cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` statements.
- The statement following `FOR EACH ROW` defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement. In the example, the triggered statement is a simple `SET` that accumulates the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
```

```
| 1852.48 |
+-----+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

Triggers for a table are also dropped if you drop the table.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activation time and activation event. For example, you cannot define two `BEFORE INSERT` triggers or two `AFTER UPDATE` triggers for a table. This should rarely be a significant limitation, because it is possible to define a trigger that executes multiple statements by using the `BEGIN . . . END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

The `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. (`OLD` and `NEW` are not case sensitive.) In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. A column named with `NEW` can be referred to if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

`OLD` and `NEW` are MySQL extensions to triggers.

By using the `BEGIN . . . END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is allowed within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value needs to be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
-> FOR EACH ROW
-> BEGIN
-> IF NEW.amount < 0 THEN
-> SET NEW.amount = 0;
-> ELSEIF NEW.amount > 100 THEN
-> SET NEW.amount = 100;
-> END IF;
-> END; //
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to invoke the same routine from within several triggers.

There are some limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are allowed to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.

- A **BEFORE** trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An **AFTER** trigger is executed only if the **BEFORE** trigger (if any) and the row operation both execute successfully.
- An error during either a **BEFORE** or **AFTER** trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For non-transactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

---

# Chapter 24. Event Scheduler

This chapter describes the *MySQL Event Scheduler*, for which support was added in MySQL 5.1.6, and is divided into the following sections:

- [Section 24.1, “Event Scheduler Overview”](#), provides an introduction to and conceptual overview of MySQL Events.
- [Section 24.2, “Event Scheduler Syntax”](#), discusses the SQL statements introduced in MySQL 5.1.6 for creating, altering, and dropping MySQL Events.
- [Section 24.3, “Event Metadata”](#), shows how to obtain information about events and how this information is stored by the MySQL Server.
- [Section 24.5, “The Event Scheduler and MySQL Privileges”](#), discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.
- [Section 24.6, “Event Scheduler Limitations and Restrictions”](#), describes the restrictions and limitations on the use of events.

**Additional Resources.** You may find the [MySQL Event Scheduler User Forum](#) of use when working with scheduled events. Here you can discuss the MySQL Event Scheduler with other MySQL users and the MySQL developers.

## 24.1. Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `crontab` (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* in order to avoid confusion with triggers of the type discussed in [Chapter 23, Triggers](#). Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL 5.1.12 and later, an event is uniquely identified by its name and the schema to which it is assigned. (Previously, an event was also unique to its definer.)
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN . . . END` block if desired (see [Section 22.2.5, “BEGIN . . . END Compound Statement Syntax”](#)). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)
- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event's action fails. See [Section 24.5, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 24.2.1, “ALTER EVENT Syntax”](#).

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. (Prior to MySQL 5.1.12, only an event's definer, or a user having privileges on the `mysql.event` table, could modify a given event.) See [Section 24.5, “The Event Scheduler and MySQL Privileges”](#).

- An event's action statement may include most SQL statements permitted within stored routines.

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` system variable determines whether the Event Scheduler is enabled and running on the server. Beginning with MySQL 5.1.12, it has one of these 3 values, which affect event scheduling as described here:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. **OFF** is the default value for `event_scheduler`.

When the Event Scheduler is stopped (`event_scheduler` is **OFF**), it can be started by setting the value of `event_scheduler` to **ON**. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is **ON**, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
 Id: 1
 User: root
 Host: localhost
 db: NULL
 Command: Query
 Time: 0
 State: NULL
 Info: show processlist
***** 2. row *****
 Id: 2
 User: event_scheduler
 Host: localhost
 db: NULL
 Command: Daemon
 Time: 3
 State: Waiting for next activation
 Info: NULL
2 rows in set (0.00 sec)
```

Event scheduling can be stopped by setting the value of `event_scheduler` to **OFF**.

- **DISABLED**: This value renders the Event Scheduler non-operational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to **DISABLED**, `event_scheduler` can be toggled between **ON** and **OFF** (using `SET`). It is also possible to use `0` for **OFF**, and `1` for **ON** when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;
```

Although **ON** and **OFF** have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of **OFF**, **ON**, or **DISABLED**. *DISABLED has no numeric equivalent*. For this reason, **ON** and **OFF** are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```
mysql< SET @@event_scheduler = OFF;
ERROR 1229 (HY000): VARIABLE 'EVENT_SCHEDULER' IS A GLOBAL
VARIABLE AND SHOULD BE SET WITH SET GLOBAL
```

## Important

It is possible to set the Event Scheduler to **DISABLED** only at server startup. If `event_scheduler` is **ON** or **OFF**,

you cannot set it to `DISABLED` at runtime. Also, if the Event Scheduler is set to `DISABLED` at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event_scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

### Note

You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

In MySQL 5.1.11, `event_scheduler` behaved as follows: this variable could take one of the values `0` (or `OFF`), `1` (or `ON`), or `2`. Setting it to `0` turned event scheduling off, so that the event scheduler thread did not run; the `event_scheduler` variable could not be set to this value while the server was running. Setting it to `1` so that the event scheduler thread ran and executed scheduled events. In this state, the event scheduler thread appeared to be sleeping when viewed with `SHOW PROCESSLIST`. When `event_scheduler` was set to `2` (which was the default value), the Event Scheduler was considered to be “suspended”; the event scheduler thread ran and could be seen in the output of `SHOW PROCESSLIST` (where `Suspended` was displayed in the `State` column), but did not execute any scheduled events. The value of `event_scheduler` could be changed only between `1` (or `ON`) and `2` while the server was running. Setting it to `0` (or `OFF`) required a server restart, as did changing its value from `0` (or `OFF`) to `1` (or `ON`) or `2`.

Prior to MySQL 5.1.11, `event_scheduler` could take one of only the 2 values `0|OFF` or `1|ON`, and the default value was `0|OFF`. It was also possible to start and stop the event scheduler thread while the MySQL server was running.

For more information concerning the reasons for these changes in behaviour, see [Bug#17619](#).

Beginning with MySQL 5.1.17, starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file ([Bug#26807](#)).

For SQL statements used to create, alter, and drop events, see [Section 24.2, “Event Scheduler Syntax”](#).

MySQL 5.1.6 and later provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 24.3, “Event Metadata”](#), and [Section 26.20, “The INFORMATION\\_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 24.5, “The Event Scheduler and MySQL Privileges”](#).

## 24.2. Event Scheduler Syntax

MySQL 5.1.6 and later provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 24.2.2, “CREATE EVENT Syntax”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 24.2.1, “ALTER EVENT Syntax”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 24.2.3, “DROP EVENT Syntax”](#). (Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 24.2.2, “CREATE EVENT Syntax”](#).)

An event can be deleted by any user having the `EVENT` privilege for the database on which the event is defined. Prior to

MySQL 5.1.12, a user other than the definer required privileges on the `mysql.event` table. See [Section 24.5, “The Event Scheduler and MySQL Privileges”](#).

## 24.2.1. ALTER EVENT Syntax

```
ALTER
[DEFINER = { user | CURRENT_USER }]
EVENT event_name
[ON SCHEDULE schedule]
[ON COMPLETION [NOT] PRESERVE]
[RENAME TO new_event_name]
[ENABLE | DISABLE | DISABLE ON SLAVE]
[COMMENT 'comment']
[DO sql_statement]
```

The `ALTER EVENT` statement is used to change one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See [Section 24.2.2, “CREATE EVENT Syntax”](#).)

Support for the `DEFINER` clause was added in MySQL 5.1.17.

Beginning with MySQL 5.1.12, any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

(In MySQL 5.1.11 and earlier, an event could be altered only by its definer, or by a user having the `SUPER` privilege.)

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
> ON SCHEDULE
> EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): UNKNOWN EVENT 'NO_SUCH_EVENT'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
ON SCHEDULE
EVERY 6 HOUR
COMMENT 'A sample comment.'
DO
UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
ON SCHEDULE
EVERY 12 HOUR
STARTS CURRENT_TIMESTAMP + 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER TABLE myevent
ON SCHEDULE
AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO
TRUNCATE TABLE myschema.mytable;
```

It is necessary to include only those options in an `ALTER EVENT` statement which correspond to characteristics that you actually wish to change; options which are omitted retain their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You may not use stored routines or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. Beginning with MySQL 5.1.13, references to stored routines, user-defined functions, and tables

in such cases are specifically disallowed, and fail with an error (see [Bug#22830](#)).

An `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
 RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
 RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `olddb` and `newdb` databases.

### Note

There is no `RENAME EVENT` statement.

Beginning with MySQL 5.1.18, a third value may also appear in place of `ENABLED` or `DISABLED`; `DISABLE ON SLAVE` is used on a replication slave to indicate an event which was created on the master and replicated to the slave, but which is not executed on the slave. Normally, `DISABLE ON SLAVE` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See [Section 18.3.1.5, “Replication of Invoked Features”](#), for more information.

## 24.2.2. CREATE EVENT Syntax

```
CREATE
 [DEFINER = { user | CURRENT_USER }]
 EVENT
 [IF NOT EXISTS]
 event_name
 ON SCHEDULE schedule
 [ON COMPLETION [NOT] PRESERVE]
 [ENABLE | DISABLE | DISABLE ON SLAVE]
 [COMMENT 'comment']
 DO sql_statement;

schedule:
 AT timestamp [+ INTERVAL interval] ...
 | EVERY interval
 | [STARTS timestamp [+ INTERVAL interval] ...]
 | [ENDS timestamp [+ INTERVAL interval] ...]

interval:
 quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
 WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
 DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}
```

This statement creates and schedules a new event. The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in the current schema. (Prior to MySQL 5.1.12, the event name needed to be unique only among events created by the same user on a given database.)
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
 ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
 DO
 UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once — one hour following its creation — by running a SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. It may be delimited using back

ticks, and may be qualified with the name of a database schema. An event is associated with both a MySQL user (the definer) and a schema, and its name must be unique among names of events within that schema. In general, the rules governing event names are the same as those for names of stored routines. See [Section 8.2, “Schema Object Names”](#).

If no schema is indicated as part of *event\_name*, the default (current) schema is assumed.

### Note

MySQL uses case-insensitive comparisons when checking for the uniqueness of event names. This means that, for example, you cannot have two events named `myevent` and `MyEvent` in the same database schema.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If a *user* value is given, it should be a MySQL account in '*user\_name*'@'*host\_name*' format (the same format used in the `GRANT` statement). The *user\_name* and *host\_name* values both are required. The definer can also be given as `CURRENT_USER` or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE EVENT` statement. (This is the same as `DEFINER = CURRENT_USER`.)

The `DEFINER` clause was added in MySQL 5.1.17. (Prior to MySQL 5.1.12, it was possible for two different users to create different events having the same name on the same database schema.)

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named *event\_name* already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the *sql\_statement* defined for the event repeats. This clause takes one of two forms:

- `AT timestamp` is used for a one-time event. It specifies that the event executes one time only at the date and time given by *timestamp*, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+-----+
| NOW() |
+-----+
| 2006-02-10 23:59:01 |
+-----+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
-> ON SCHEDULE AT '2006-02-10 23:59:00'
-> DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT
PRESERVE is set. The event was dropped immediately after
creation.
```

`CREATE EVENT` statements which are themselves invalid — for whatever reason — fail with an error.

You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time — such as that expressed by the phrase “three weeks from now” — you can use the optional clause `+ INTERVAL interval`. The *interval* portion consists of two parts, a quantity and a unit of time, and follows the same syntax rules that govern intervals used in the `DATE_ADD()` function (see [Section 11.6, “Date and Time Functions”](#)). The units keywords are also the same, except that you cannot use any units involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an `EVERY` clause. The `EVERY` keyword is followed by an *interval* as described in the previous discussion of the `AT` keyword. (`+ INTERVAL` is *not* used with `EVERY`.) For example, `EVERY 6 WEEK` means “every six weeks”.

Although `+ INTERVAL` clauses are not allowed in an `EVERY` clause, you can use the same complex time units allowed in a `+ INTERVAL`.

An `EVERY` clause may also contain an optional `STARTS` clause. `STARTS` is followed by a *timestamp* value which indicates

when the action should begin repeating, and may also use `+ INTERVAL interval` in order to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP` — that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may also contain an optional `ENDS` clause. The `ENDS` keyword is followed by a *timestamp* value which tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` with `ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

`ENDS` supports the same syntax for complex time units as `STARTS` does.

You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

### Note

Beginning with MySQL 5.1.17, `STARTS` or `ENDS` uses the MySQL server's local time zone, as shown in the `INFORMATION_SCHEMA.EVENTS` and `mysql.event` tables, as well as in the output of `SHOW EVENTS`. Previously, this information was stored using UTC ([Bug#16420](#)).

Due to this change, the `mysql.event` table must be updated before events created in earlier releases can be created, altered, viewed, or used in MySQL 5.1.17 or later. You can use `mysql_upgrade` for this (see [Section 4.4.8](#), “`mysql_upgrade` — Check Tables for MySQL Upgrade”).

See [Section 26.20](#), “The `INFORMATION_SCHEMA.EVENTS` Table”, and [Section 12.5.4.16](#), “`SHOW EVENTS`” for information about columns added in MySQL 5.1.17 to accommodate these changes.

Beginning with MySQL 5.1.18, a third value may also appear in place of `ENABLED` or `DISABLED`; `DISABLE ON SLAVE` is set for the status of an event on a replication slave to indicate that the event was created on the master and replicated to the slave, but is not executed on the slave. See [Section 18.3.1.5](#), “Replication of Invoked Features”.

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `CREATE EVENT` and `ALTER EVENT` statements. Beginning with MySQL 5.1.13, references to stored functions, user-defined functions, and tables in such cases are specifically disallowed, and fail with an error (see [Bug#22830](#)).

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying `ON COMPLETION PRESERVE`. Using `ON COMPLETION NOT PRESERVE` merely makes the default non-persistent behavior explicit.

You can create an event but keep it from being active using the `DISABLE` keyword. Alternatively, you may use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see [Section 24.2.1](#), “`ALTER EVENT Syntax`”).

You may supply a comment for an event using a `COMMENT` clause. *comment* may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement which can be used in a stored routine can also be used as the action statement for a scheduled event. (See [Section D.1](#), “Restrictions on Stored Routines, Triggers, and Events”.) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
EVERY 1 HOUR
COMMENT 'Clears out sessions table each hour.'
DO
DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` system variable setting that is in effect at the time an event is created, and always executes the event with this setting in force, *regardless of the current server SQL mode*.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

### Note

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name. (In MySQL 5.1.6, all tables referenced in event `DO` clauses had to include a reference to the schema.)

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```
DELIMITER |
CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day.'
DO
BEGIN
INSERT INTO site_activity.totals (when, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END |
DELIMITER ;
```

Note the use of the `DELIMITER` command to change the statement delimiter, as with stored routines. See [Section 22.2.1, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
DELIMITER |
CREATE EVENT e
ON SCHEDULE
EVERY 5 SECOND
DO
BEGIN
DECLARE v INTEGER;
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;

SET v = 0;

WHILE v < 5 DO
INSERT INTO t1 VALUES (0);
UPDATE t2 SET s1 = s1 + 1;
SET v = v + 1;
END WHILE;
END |
DELIMITER ;
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters:

```
CREATE EVENT e_call_myproc
ON SCHEDULE
AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);
```

In addition, if the event's definer has the `SUPER` privilege, that event may read and write global variables. As granting this privilege entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements which are valid in stored routines may be used for action statements executed by events. For more information about statements allowable within stored routines, see [Section 22.2, “Stored Routine Syntax”](#). You can create an event as part of a stored routine, but an event cannot be created by another event.

### 24.2.3. DROP EVENT Syntax

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named *event\_name*. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): UNKNOWN EVENT 'EVENT_NAME'` results. You can override this and cause the statement to generate a warning for non-existent events instead using `IF EXISTS`.

Beginning with MySQL 5.1.12, an event can be dropped by any user having the `EVENT` privilege on the database schema to which the event to be dropped belongs. (In MySQL 5.1.11 and earlier, an event could be dropped only by its definer, or by a user having the `SUPER` privilege.)

## 24.3. Event Metadata

Information about events can be obtained as follows:

- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See [Section 26.20, “The INFORMATION\\_SCHEMA EVENTS Table”](#).
- Use the `SHOW EVENTS` statement. See [Section 12.5.4.16, “SHOW EVENTS”](#).
- Use the `SHOW CREATE EVENT` statement. See [Section 12.5.4.7, “SHOW CREATE EVENT”](#).
- A record of events executed on the server can be read from the MySQL Server's error log. See [Section 24.5, “The Event Scheduler and MySQL Privileges”](#) for an example.

## 24.4. Event Scheduler Status

Information about the state of the Event Scheduler for debugging and troubleshooting purposes can be obtained as follows:

- In MySQL 5.1.11 `-debug` builds, you can use the `SHOW SCHEDULER STATUS` statement; see [Section 12.5.4.26, “SHOW SCHEDULER STATUS Syntax”](#).

### Important

This statement was removed in MySQL 5.1.12. We intend to implement an SQL statement providing similar functionality in a future MySQL release.

- Beginning with MySQL 5.1.12, event scheduler status information can be obtained by running `mysqladmin debug` (see [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#)); after running this command, the error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At LUA = Last Unlocked At
WOC = Waiting On Condition DL = Data Locked

Event scheduler status:
State : INITIALIZED
Thread id : 0
LLA : init_scheduler:313
LUA : init_scheduler:318
WOC : NO
Workers : 0
Executed : 0
Data locked: NO

Event queue status:
Element count : 1
Data locked : NO
Attempting lock : NO
LLA : init_queue:148
LUA : init_queue:168
WOC : NO
Next activation : 0000-00-00 00:00:00
```

## 24.5. The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires the `SUPER` privilege.

MySQL 5.1.6 introduces a privilege governing the creation, modification, and deletion of events, the `EVENT` privilege. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): ILLEGAL GRANT/REVOKE COMMAND; PLEASE
CONSULT THE MANUAL TO SEE WHICH PRIVILEGES CAN BE USED
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
ON SCHEDULE
EVERY 10 SECOND
DO
INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, he finds that the table is empty. Since he does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```
060209 22:39:44 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:44 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:39:54 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:54 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:40:04 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:40:04 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
```

Since this user very likely does not have access to the error log, he can verify whether the event's action statement is valid by running it himself:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT COMMAND DENIED TO USER
'JON'@'GHIDORA' FOR TABLE 'MYTABLE'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: INTERVAL_SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

## Note

Prior to MySQL 5.1.12, there was no `EVENT_DEFINITION` column, and `EVENT_BODY` contained the SQL statement or statements to be executed. See [Section 26.20, “The INFORMATION\\_SCHEMA EVENTS Table”](#), for more information.

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

### Important

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

For example, suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
ON SCHEDULE
EVERY 7 SECOND
DO
INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see [Section 26.20](#), “The `INFORMATION_SCHEMA.EVENTS` Table”) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table, which was added in MySQL 5.1.6. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
WHERE db = 'myschema'
AND definer = 'jon@ghidora'
AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

### Note

The namespace for scheduled events changed in MySQL 5.1.12. Prior to that MySQL version, different users could create different events having the same name in the same database; in MySQL 5.1.12 and later, that is no longer the case. When upgrading to MySQL 5.1.12 or later from MySQL 5.1.11 or earlier, it is extremely important to make sure that no events in the same database share the same name, *prior to performing the upgrade*.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statement perform the required operations on them.

MySQL 5.1.6 introduces five status variables providing counts of event-related operations (but *not* of statements executed by events — see [Section 24.6](#), “Event Scheduler Limitations and Restrictions”). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

## 24.6. Event Scheduler Limitations and Restrictions

This section lists restrictions and limitations applying to event scheduling in MySQL 5.1.

**Qualification of identifiers.** In MySQL 5.1.6 only, any table referenced in an event's action statement must be fully qualified with the name of the schema in which it occurs (that is, as `schema_name.table_name`).

**Case sensitivity of event identifiers.** Beginning with MySQL 5.1.8, event names are handled in case-insensitive fashion. For example, this means that you cannot have two events in the same database (and — prior to MySQL 5.1.12 — with the same definer) with the names `anEvent` and `AnEvent`.

### Important

If you have events created in MySQL 5.1.7 or earlier which are assigned to the same database and have the same definer, and whose names differ only with respect to lettercase, then you must rename these events to respect case-sensitive handling before upgrading to MySQL 5.1.8 or later.

**Modification of events by stored routines and triggers.** An event may not be created, altered, or dropped by a trigger, stored routine, or another event. An event also may not create, alter, or drop triggers or stored routines. ([Bug#16409](#), [Bug#18896](#))

**Resolution of event timings.** Event timings using the intervals `YEAR`, `QUARTER`, `MONTH`, and `YEAR_MONTH` are resolved in months; those using any other interval are resolved in seconds. There is no way to cause events scheduled to occur at the same second to execute in a given order. In addition — due to rounding, the nature of threaded applications, and the fact that a non-zero length of time is required to create events and to signal their execution — events may be delayed by as much as 1 or 2 seconds. However, the time shown in the `INFORMATION_SCHEMA.EVENTS` table's `LAST_EXECUTED` column or the `mysql.event` table's `last_executed` column is always accurate to within one second of the time the event was actually executed. (See also [Bug#16522](#).)

**Effects on statement counts.** Each execution of the statements contained in the body of an event takes place in a new connection; thus, these statements has no effect in a given user session on the server's statement counts such as `Com_select` and `Com_insert` that are displayed by `SHOW STATUS`. However, such counts *are* updated in the global scope. ([Bug#16422](#))

**Visibility of events belonging to other users.** Prior to MySQL 5.1.12, you could not view another user's events in the `INFORMATION_SCHEMA.EVENTS` table. In other words, any query made against this table was treated as though it contained the condition `DEFINER = CURRENT_USER()` in the `WHERE` clause.

**Start times.** Events cannot be created with a start time that is in the past.

**Latest time supported.** Events do not support times later than the end of the Unix Epoch; this is approximately the beginning of the year 2038. Prior to MySQL 5.1.8, handling in scheduled events of dates later than this was buggy; starting with MySQL 5.1.8, such dates are specifically disallowed by the Event Scheduler. ([Bug#16396](#))

**Server SQL mode.** In MySQL 5.1.6, `INFORMATION_SCHEMA.EVENTS` shows `NULL` in the `SQL_MODE` column. Beginning with MySQL 5.1.7, the `SQL_MODE` displayed is that in effect when the event was created.

**Dropping or altering events.** In MySQL 5.1.6, the only way to drop or alter an event created by a user who was not the definer of that event was by manipulation of the `mysql.event` system table by the MySQL `root` user or by another user with privileges on this table. Beginning with MySQL 5.1.7, `DROP USER` drops all events for which that user was the definer; also beginning with MySQL 5.1.7 `DROP SCHEMA` drops all events associated with the dropped schema.

**Database object references in `ON SCHEDULE` clauses.** References to stored functions, user-defined functions, and tables in the `ON SCHEDULE` clauses of `CREATE EVENT` and `ALTER EVENT` statements are not supported. Beginning with MySQL 5.1.13, these sorts of references are disallowed. (See [Bug#22830](#) for more information.)

**Disallowed statements.** Generally speaking, statements which are not permitted in stored routines or in SQL prepared statements are also not allowed in the body of an event. See [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#), and [Section 12.7, “SQL Syntax for Prepared Statements”](#), for more information.

**Upgrading to MySQL 5.1.18 or later.** When upgrading to MySQL 5.1.18 or later from a previous MySQL version where scheduled events were in use, the upgrade utilities `mysql_upgrade` and `mysql_fix_privilege_tables` do not accommodate changes in system tables relating to the Event Scheduler. As a workaround, you can dump events before the upgrade, then restore them from the dump afterwards. This issue was fixed in MySQL 5.1.20 (see [Bug#28521](#)).

---

## Chapter 25. Views

Views (including updatable views) are available in MySQL Server 5.1.

Answers to some frequently asked questions concerning views in MySQL 5.1 can be found in [Section A.6, “MySQL 5.1 FAQ — Views”](#).

This chapter discusses the following topics:

- Creating or altering views with `CREATE VIEW` or `ALTER VIEW`
- Destroying views with `DROP VIEW`

Discussion of restrictions on use of views is given in [Section D.4, “Restrictions on Views”](#).

To use views if you have upgraded to MySQL 5.1 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

Metadata about views can be obtained from the `INFORMATION_SCHEMA.VIEWS` table and by using the `SHOW CREATE VIEW` statement. See [Section 26.15, “The INFORMATION\\_SCHEMA VIEWS Table”](#), and [Section 12.5.4.11, “SHOW CREATE VIEW Syntax”](#).

### 25.1. ALTER VIEW Syntax

```
ALTER
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` and the effect is the same as for `CREATE OR REPLACE VIEW`. See [Section 25.2, “CREATE VIEW Syntax”](#). This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. As of MySQL 5.1.23, `ALTER VIEW` is allowed only to the definer or users with the `SUPER` privilege.

### 25.2. CREATE VIEW Syntax

```
CREATE
[OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing one if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` is the same as `ALTER VIEW`.

The `select_statement` is a `SELECT` statement that provides the definition of the view. (When you select from the view, you select in effect using the `SELECT` statement.) `select_statement` can select from base tables or other views.

The view definition is “frozen” at creation time, so changes to the underlying tables afterward do not affect the view definition. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, specify the name as `db_name.view_name` when you create it.

```
mysql> CREATE VIEW test.v AS SELECT * FROM t;
```

Base tables and views share the same namespace within a database, so a database cannot contain a base table and a view that have the same name.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, the optional `column_list` clause can be given as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

When you modify an existing view, the current view definition is backed up and saved. It is stored in that table's database directory, in a sub-folder named `arc`. The backup file will be named `view_name.frm-00001`. If you alter the view again, the next backup will be named `view_name.frm-00002`. The three latest view backup definitions will be stored.

### Note

Backed up view definitions will not be preserved by `mysqldump`, or any other such programs, but you could retain it from a file copy. However, they are not needed for anything, but to provide you with a backup of your previous view definition.

Also note that while it is safe to remove these, it is not safe to do so while `mysqld` is running. If you delete this folder (or sub-files) while `mysqld` is running, you will receive an error the next time you try to alter that view:

```
mysql> ALTER VIEW v AS SELECT * FROM t;
ERROR 6 (HY000): Error on delete of './test\arc/v.frm-0004' (Errcode:
2)
```

Columns retrieved by the `SELECT` statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Unqualified table or view names in the `SELECT` statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3 | 50 | 150 |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system or user variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Within a stored routine, the definition cannot refer to routine parameters or local variables.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. In this case, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- The tables named in the view definition must already exist.
- You cannot associate a trigger with a view.

`ORDER BY` is allowed in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

If you create a view and then change the query processing environment by changing system variables, that may affect the results that you get from the view:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| mycol |
+-----+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| abc |
+-----+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. They were added in MySQL 5.1.2. The legal `SQL SECURITY` characteristic values are `DEFINER` and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively. The default `SQL SECURITY` value is `DEFINER`.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account in '`user_name`'@'`host_name`' format (the same format used in the `GRANT` statement). The `user_name` and `host_name` values both are required. The definer can also be given as `CURRENT_USER` or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

If the `SQL SECURITY` value is `DEFINER` but the definer account does not exist when the view is referenced, an error occurs.

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine creator. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

As of MySQL 5.1.2 (when the `DEFINER` and `SQL SECURITY` clauses were implemented), view privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have privileges for the columns, as described previously. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required when the function runs can be checked only as it executes: For different invocations of the function, different execution paths within the function might be taken.
- When a view is referenced, privileges for objects accessed by the view are checked against the privileges held by the view creator or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depends on whether the function is defined with a `SQL SECURITY` characteristic of `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges of its creator. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Prior to MySQL 5.1.2 (before the `DEFINER` and `SQL SECURITY` clauses were implemented), privileges required for objects used in a view are checked at view creation time.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
 CALL p1();
ELSE
 CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the view `v` and the function `f()`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY INVOKER`.

If you invoke a view that was created before MySQL 5.1.2, it is treated as though it was created with a `SQL SECURITY DEFINER` clause and with a `DEFINER` value that is the same as your account. However, because the actual definer is unknown, MySQL issues a warning. To make the warning go away, it is sufficient to re-create the view so that the view definition includes a `DEFINER` clause.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`

- \* becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

The `MERGE` algorithm requires a one-to-one relationship between the rows in the view and the rows in the underlying table. If this relationship does not hold, a temporary table must be used instead. Lack of a one-to-one relationship occurs if the view contains any of a number of constructs:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Refers only to literal values (in this case, there is no underlying table)

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Non-updatable view in the `FROM` clause
- A subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view non-updatable)

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is allowable:

```
UPDATE v SET col1 = 0;
```

This update is not allowable because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a `UNION`). Also, only a single table in the view definition can be updated, so the `SET` clause must name only columns from one of the tables in the view. Views that use `UNION ALL` are disallowed even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADE` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADE` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADE`. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
-> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
-> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
-> WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADE` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the

---

`INFORMATION_SCHEMA.VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See [Section 5.1.3, “System Variables”](#).

## 25.3. DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
 view_name [, view_name] ...
 [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view. If any of the views named in the argument list do not exist, MySQL returns an error indicating by name which non-existing views it was unable to drop, but it also drops all of the views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each non-existent view. See [Section 12.5.4.32, “SHOW WARNINGS Syntax”](#).

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

---

## Chapter 26. INFORMATION\_SCHEMA Tables

`INFORMATION_SCHEMA` provides access to database metadata.

*Metadata* is data about the data, such as the name of a database or table, the data type of a column, or access privileges. Other terms that sometimes are used for this information are *data dictionary* and *system catalog*.

`INFORMATION_SCHEMA` is the information database, the place that stores information about all the other databases that the MySQL server maintains. Inside `INFORMATION_SCHEMA` there are several read-only tables. They are actually views, not base tables, so there are no files associated with them.

In effect, we have a database named `INFORMATION_SCHEMA`, although the server does not create a database directory with that name. It is possible to select `INFORMATION_SCHEMA` as the default database with a `USE` statement, but it is possible only to read the contents of tables. You cannot insert into them, update them, or delete from them.

Here is an example of a statement that retrieves information from `INFORMATION_SCHEMA`:

```
mysql> SELECT table_name, table_type, engine
-> FROM information_schema.tables
-> WHERE table_schema = 'db5'
-> ORDER BY table_name DESC;
```

| table_name | table_type | engine |
|------------|------------|--------|
| v56        | VIEW       | NULL   |
| v3         | VIEW       | NULL   |
| v2         | VIEW       | NULL   |
| v          | VIEW       | NULL   |
| tables     | BASE TABLE | MyISAM |
| t7         | BASE TABLE | MyISAM |
| t3         | BASE TABLE | MyISAM |
| t2         | BASE TABLE | MyISAM |
| t          | BASE TABLE | MyISAM |
| pk         | BASE TABLE | InnoDB |
| loop       | BASE TABLE | MyISAM |
| kurs       | BASE TABLE | MyISAM |
| k          | BASE TABLE | MyISAM |
| into       | BASE TABLE | MyISAM |
| goto       | BASE TABLE | MyISAM |
| fk2        | BASE TABLE | InnoDB |
| fk         | BASE TABLE | InnoDB |

17 rows in set (0.01 sec)

Explanation: The statement requests a list of all the tables in database `db5`, in reverse alphabetical order, showing just three pieces of information: the name of the table, its type, and its storage engine.

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges will see `NULL`.

The `SELECT . . . FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules. That is, all access is done on tables.
- Nobody needs to learn a new statement syntax. Because they already know how `SELECT` works, they only need to learn the object names.
- The implementor need not worry about adding keywords.
- There are millions of possible output variations, instead of just one. This provides more flexibility for applications that have varying requirements about what metadata they need.
- Migration is easier because every other DBMS does it this way.

However, because `SHOW` is popular with MySQL employees and users, and because it might be confusing were it to disappear, the advantages of conventional syntax are not a sufficient reason to eliminate `SHOW`. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as well. These are described in [Section 26.27, "Extensions to SHOW Statements"](#).

There is no difference between the privileges required for `SHOW` statements and those required to select information from `INFORMATION_SCHEMA`. In either case, you have to have some privilege on an object in order to see information about it.

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

The following sections describe each of the tables and columns that are in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA Name`” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW Name`” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: <http://web.archive.org/web/20030201202307/www.dbazine.com/gulutzan5.html>.

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns. If the default collation is not correct for your needs, you can force a suitable collation with a `COLLATE` clause (Section 9.1.5.1, “Using `COLLATE` in SQL Statements”).

Each section indicates what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`, if there is such a statement.

### Note

At present, there are some missing columns and some columns out of order. We are working on this and updating the documentation as changes are made.

For answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database, see Section A.7, “MySQL 5.0 FAQ — `INFORMATION_SCHEMA`”.

## 26.1. The `INFORMATION_SCHEMA.SCHEMATA` Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

| <code>INFORMATION_SCHEMA Name</code>    | <code>SHOW Name</code> | Remarks           |
|-----------------------------------------|------------------------|-------------------|
| <code>CATALOG_NAME</code>               |                        | <code>NULL</code> |
| <code>SCHEMA_NAME</code>                |                        | Database          |
| <code>DEFAULT_CHARACTER_SET_NAME</code> |                        |                   |
| <code>DEFAULT_COLLATION_NAME</code>     |                        |                   |
| <code>SQL_PATH</code>                   |                        | <code>NULL</code> |

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
[LIKE 'wild']
```

## 26.2. The `INFORMATION_SCHEMA.TABLES` Table

The `TABLES` table provides information about tables in databases.

| INFORMATION_SCHEMA Name | SHOW Name       | Remarks                                                      |
|-------------------------|-----------------|--------------------------------------------------------------|
| TABLE_CATALOG           |                 | NULL                                                         |
| TABLE_SCHEMA            | Table_...       |                                                              |
| TABLE_NAME              | Table_...       |                                                              |
| TABLE_TYPE              |                 |                                                              |
| ENGINE                  | Engine          | MySQL extension                                              |
| VERSION                 | Version         | The version number of the table's .frm file, MySQL extension |
| ROW_FORMAT              | Row_format      | MySQL extension                                              |
| TABLE_ROWS              | Rows            | MySQL extension                                              |
| AVG_ROW_LENGTH          | Avg_row_length  | MySQL extension                                              |
| DATA_LENGTH             | Data_length     | MySQL extension                                              |
| MAX_DATA_LENGTH         | Max_data_length | MySQL extension                                              |
| INDEX_LENGTH            | Index_length    | MySQL extension                                              |
| DATA_FREE               | Data_free       | MySQL extension                                              |
| AUTO_INCREMENT          | Auto_increment  | MySQL extension                                              |
| CREATE_TIME             | Create_time     | MySQL extension                                              |
| UPDATE_TIME             | Update_time     | MySQL extension                                              |
| CHECK_TIME              | Check_time      | MySQL extension                                              |
| TABLE_COLLATION         | Collation       | MySQL extension                                              |
| CHECKSUM                | Checksum        | MySQL extension                                              |
| CREATE_OPTIONS          | Create_options  | MySQL extension                                              |
| TABLE_COMMENT           | Comment         | MySQL extension                                              |

**Notes:**

- `TABLE_SCHEMA` and `TABLE_NAME` are a single field in a `SHOW` display, for example `Table_in_db1`.
- `TABLE_TYPE` should be `BASE TABLE` or `VIEW`. Currently, the `TABLES` table does not list `TEMPORARY` tables.
- For partitioned tables, beginning with MySQL 5.1.9, the `ENGINE` column shows the name of the storage engine used by all partitions. (Previously, this column showed `PARTITION` for such tables.)
- The `TABLE_ROWS` column is `NULL` if the table is in the `INFORMATION_SCHEMA` database. For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization.
- For tables using the `NDBCLUSTER` storage engine, beginning with MySQL 5.1.12, the `DATA_LENGTH` column reflects the true amount of storage for variable-width columns. (See [Bug#18413](#).)

**Note**

Because MySQL Cluster allocates storage for variable-width columns in 10-page extents of 32 kilobytes each, space usage for such columns is reported in increments of 320 KB.

- Beginning with MySQL 5.1.24, the `DATA_FREE` column shows the free space in bytes for `InnoDB` tables. ([Bug#32440](#))
- We have nothing for the table's default character set. `TABLE_COLLATION` is close, because collation names begin with a character set name.
- Beginning with MySQL 5.1.9, the `CREATE_OPTIONS` column shows `partitioned` if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']

SHOW TABLES
FROM db_name
[LIKE 'wild']
```

## 26.3. The INFORMATION\_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables.

| INFORMATION_SCHEMA Name  | SHOW Name | Remarks         |
|--------------------------|-----------|-----------------|
| TABLE_CATALOG            |           | NULL            |
| TABLE_SCHEMA             |           |                 |
| TABLE_NAME               |           |                 |
| COLUMN_NAME              | Field     |                 |
| ORDINAL_POSITION         |           | see notes       |
| COLUMN_DEFAULT           | Default   |                 |
| IS_NULLABLE              | Null      |                 |
| DATA_TYPE                | Type      |                 |
| CHARACTER_MAXIMUM_LENGTH | Type      |                 |
| CHARACTER_OCTET_LENGTH   |           |                 |
| NUMERIC_PRECISION        | Type      |                 |
| NUMERIC_SCALE            | Type      |                 |
| CHARACTER_SET_NAME       |           |                 |
| COLLATION_NAME           | Collation |                 |
| COLUMN_TYPE              | Type      | MySQL extension |
| COLUMN_KEY               | Key       | MySQL extension |
| EXTRA                    | Extra     | MySQL extension |
| COLUMN_COMMENT           | Comment   | MySQL extension |

### Notes:

- In `SHOW`, the `Type` display includes values from several different `COLUMNS` columns.
- `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW`, `SELECT` does not have automatic ordering.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multi-byte character sets.
- `CHARACTER_SET_NAME` can be derived from `Collation`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `Collation` column a value of `latin1_swedish_ci`, the character set is what's before the first underscore: `latin1`.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

## 26.4. The INFORMATION\_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks    |
|-------------------------|-----------|------------|
| TABLE_CATALOG           |           | NULL       |
| TABLE_SCHEMA            |           | = Database |

|              |              |                 |
|--------------|--------------|-----------------|
| TABLE_NAME   | Table        |                 |
| NON_UNIQUE   | Non_unique   |                 |
| INDEX_SCHEMA |              | = Database      |
| INDEX_NAME   | Key_name     |                 |
| SEQ_IN_INDEX | Seq_in_index |                 |
| COLUMN_NAME  | Column_name  |                 |
| COLLATION    | Collation    |                 |
| CARDINALITY  | Cardinality  |                 |
| SUB_PART     | Sub_part     | MySQL extension |
| PACKED       | Packed       | MySQL extension |
| NULLABLE     | Null         | MySQL extension |
| INDEX_TYPE   | Index_type   | MySQL extension |
| COMMENT      | Comment      | MySQL extension |

**Notes:**

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
 WHERE table_name = 'tbl_name'
 [AND table_schema = 'db_name']

SHOW INDEX
 FROM tbl_name
 [FROM db_name]
```

## 26.5. The INFORMATION\_SCHEMA USER\_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks                                        |
|-------------------------|-----------|------------------------------------------------|
| GRANTEE                 |           | 'user_name'@'host_name' value, MySQL extension |
| TABLE_CATALOG           |           | NULL, MySQL extension                          |
| PRIVILEGE_TYPE          |           | MySQL extension                                |
| IS_GRANTABLE            |           | MySQL extension                                |

**Notes:**

- This is a non-standard table. It takes its values from the `mysql.user` table.

## 26.6. The INFORMATION\_SCHEMA SCHEMA\_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks                                        |
|-------------------------|-----------|------------------------------------------------|
| GRANTEE                 |           | 'user_name'@'host_name' value, MySQL extension |

|                |  |                       |
|----------------|--|-----------------------|
| TABLE_CATALOG  |  | NULL, MySQL extension |
| TABLE_SCHEMA   |  | MySQL extension       |
| PRIVILEGE_TYPE |  | MySQL extension       |
| IS_GRANTABLE   |  | MySQL extension       |

**Notes:**

- This is a non-standard table. It takes its values from the `mysql.db` table.

## 26.7. The INFORMATION\_SCHEMA TABLE\_PRIVILEGES Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks                                         |
|-------------------------|-----------|-------------------------------------------------|
| GRANTEE                 |           | ' <i>user_name</i> '@' <i>host_name</i> ' value |
| TABLE_CATALOG           |           | NULL                                            |
| TABLE_SCHEMA            |           |                                                 |
| TABLE_NAME              |           |                                                 |
| PRIVILEGE_TYPE          |           |                                                 |
| IS_GRANTABLE            |           |                                                 |

**Notes:**

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`, `ALTER`, `INDEX`, `DROP`, `CREATE VIEW`.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

## 26.8. The INFORMATION\_SCHEMA COLUMN\_PRIVILEGES Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks                                         |
|-------------------------|-----------|-------------------------------------------------|
| GRANTEE                 |           | ' <i>user_name</i> '@' <i>host_name</i> ' value |
| TABLE_CATALOG           |           | NULL                                            |
| TABLE_SCHEMA            |           |                                                 |
| TABLE_NAME              |           |                                                 |
| COLUMN_NAME             |           |                                                 |
| PRIVILEGE_TYPE          |           |                                                 |
| IS_GRANTABLE            |           |                                                 |

**Notes:**

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`.
- If the user has `GRANT OPTION` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

## 26.9. The INFORMATION\_SCHEMA CHARACTER\_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

| INFORMATION_SCHEMA Name           | SHOW Name                      | Remarks         |
|-----------------------------------|--------------------------------|-----------------|
| <code>CHARACTER_SET_NAME</code>   | <code>Charset</code>           |                 |
| <code>DEFAULT_COLLATE_NAME</code> | <code>Default collation</code> |                 |
| <code>DESCRIPTION</code>          | <code>Description</code>       | MySQL extension |
| <code>MAXLEN</code>               | <code>Maxlen</code>            | MySQL extension |

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
 [WHERE name LIKE 'wild']
SHOW CHARACTER SET
 [LIKE 'wild']
```

## 26.10. The INFORMATION\_SCHEMA COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

| INFORMATION_SCHEMA Name         | SHOW Name              | Remarks         |
|---------------------------------|------------------------|-----------------|
| <code>COLLATION_NAME</code>     | <code>Collation</code> |                 |
| <code>CHARACTER_SET_NAME</code> | <code>Charset</code>   | MySQL extension |
| <code>ID</code>                 | <code>Id</code>        | MySQL extension |
| <code>IS_DEFAULT</code>         | <code>Default</code>   | MySQL extension |
| <code>IS_COMPILED</code>        | <code>Compiled</code>  | MySQL extension |
| <code>SORTLEN</code>            | <code>Sortlen</code>   | MySQL extension |

The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
 [WHERE collation_name LIKE 'wild']
SHOW COLLATION
 [LIKE 'wild']
```

## 26.11. The INFORMATION\_SCHEMA COLLATION\_CHARACTER\_SET\_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from `SHOW COLLATION`.

| INFORMATION_SCHEMA Name         | SHOW Name              | Remarks |
|---------------------------------|------------------------|---------|
| <code>COLLATION_NAME</code>     | <code>Collation</code> |         |
| <code>CHARACTER_SET_NAME</code> | <code>Charset</code>   |         |

## 26.12. The INFORMATION\_SCHEMA TABLE\_CONSTRAINTS Table

The `TABLE_CONSTRAINTS` table describes which tables have constraints.

| INFORMATION_SCHEMA Name         | SHOW Name | Remarks           |
|---------------------------------|-----------|-------------------|
| <code>CONSTRAINT_CATALOG</code> |           | <code>NULL</code> |
| <code>CONSTRAINT_SCHEMA</code>  |           |                   |
| <code>CONSTRAINT_NAME</code>    |           |                   |
| <code>TABLE_SCHEMA</code>       |           |                   |
| <code>TABLE_NAME</code>         |           |                   |
| <code>CONSTRAINT_TYPE</code>    |           |                   |

### Notes:

- The `CONSTRAINT_TYPE` value can be `UNIQUE`, `PRIMARY KEY`, or `FOREIGN KEY`.
- The `UNIQUE` and `PRIMARY KEY` information is about the same as what you get from the `Key_name` field in the output from `SHOW INDEX` when the `Non_unique` field is 0.
- The `CONSTRAINT_TYPE` column can contain one of these values: `UNIQUE`, `PRIMARY KEY`, `FOREIGN KEY`, `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until we support `CHECK`.

## 26.13. The INFORMATION\_SCHEMA KEY\_COLUMN\_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

| INFORMATION_SCHEMA Name                    | SHOW Name | Remarks           |
|--------------------------------------------|-----------|-------------------|
| <code>CONSTRAINT_CATALOG</code>            |           | <code>NULL</code> |
| <code>CONSTRAINT_SCHEMA</code>             |           |                   |
| <code>CONSTRAINT_NAME</code>               |           |                   |
| <code>TABLE_CATALOG</code>                 |           |                   |
| <code>TABLE_SCHEMA</code>                  |           |                   |
| <code>TABLE_NAME</code>                    |           |                   |
| <code>COLUMN_NAME</code>                   |           |                   |
| <code>ORDINAL_POSITION</code>              |           |                   |
| <code>POSITION_IN_UNIQUE_CONSTRAINT</code> |           |                   |
| <code>REFERENCED_TABLE_SCHEMA</code>       |           |                   |
| <code>REFERENCED_TABLE_NAME</code>         |           |                   |
| <code>REFERENCED_COLUMN_NAME</code>        |           |                   |

### Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of `ORDINAL_POSITION` is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of `POSITION_IN_UNIQUE_CONSTRAINT` is `NULL` for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

For example, suppose that there are two tables name `t1` and `t3` that have the following definitions:

```
CREATE TABLE t1
(
 s1 INT,
 s2 INT,
 s3 INT,
 PRIMARY KEY(s3)
```

```

) ENGINE=InnoDB;
CREATE TABLE t3
(
 s1 INT,
 s2 INT,
 s3 INT,
 KEY(s1),
 CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;

```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY'`, `TABLE_NAME = 't1'`, `COLUMN_NAME = 's3'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = NULL`.
- One row with `CONSTRAINT_NAME = 'CO'`, `TABLE_NAME = 't3'`, `COLUMN_NAME = 's2'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = 1`.

## 26.14. The INFORMATION\_SCHEMA ROUTINES Table

The `ROUTINES` table provides information about stored routines (both procedures and functions). The `ROUTINES` table does not include user-defined functions (UDFs) at this time.

The column named “`mysql.proc name`” indicates the `mysql.proc` table column that corresponds to the `INFORMATION_SCHEMA.ROUTINES` table column, if any.

| INFORMATION_SCHEMA Name           | mysql.proc Name               | Remarks                |
|-----------------------------------|-------------------------------|------------------------|
| <code>SPECIFIC_NAME</code>        | <code>specific_name</code>    |                        |
| <code>ROUTINE_CATALOG</code>      |                               | NULL                   |
| <code>ROUTINE_SCHEMA</code>       | <code>db</code>               |                        |
| <code>ROUTINE_NAME</code>         | <code>name</code>             |                        |
| <code>ROUTINE_TYPE</code>         | <code>type</code>             | {PROCEDURE   FUNCTION} |
| <code>DTD_IDENTIFIER</code>       |                               | data type descriptor   |
| <code>ROUTINE_BODY</code>         |                               | SQL                    |
| <code>ROUTINE_DEFINITION</code>   | <code>body</code>             |                        |
| <code>EXTERNAL_NAME</code>        |                               | NULL                   |
| <code>EXTERNAL_LANGUAGE</code>    | <code>language</code>         | NULL                   |
| <code>PARAMETER_STYLE</code>      |                               | SQL                    |
| <code>IS_DETERMINISTIC</code>     | <code>is_deterministic</code> |                        |
| <code>SQL_DATA_ACCESS</code>      | <code>sql_data_access</code>  |                        |
| <code>SQL_PATH</code>             |                               | NULL                   |
| <code>SECURITY_TYPE</code>        | <code>security_type</code>    |                        |
| <code>CREATED</code>              | <code>created</code>          |                        |
| <code>LAST_ALTERED</code>         | <code>modified</code>         |                        |
| <code>SQL_MODE</code>             | <code>sql_mode</code>         | MySQL extension        |
| <code>ROUTINE_COMMENT</code>      | <code>comment</code>          | MySQL extension        |
| <code>DEFINER</code>              | <code>definer</code>          | MySQL extension        |
| <code>CHARACTER_SET_CLIENT</code> |                               | MySQL extension        |
| <code>COLLATION_CONNECTION</code> |                               | MySQL extension        |
| <code>DATABASE_COLLATION</code>   |                               | MySQL extension        |

### Notes:

- MySQL calculates `EXTERNAL_LANGUAGE` thus:
  - If `mysql.proc.language = 'SQL'`, `EXTERNAL_LANGUAGE` is NULL

- Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the routine was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the routine was created. `DATABASE_COLLATION` is the collation of the database with which the routine is associated. These columns were added in MySQL 5.1.21.

## 26.15. The INFORMATION\_SCHEMA VIEWS Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` privilege to access this table.

| INFORMATION_SCHEMA Name           | SHOW Name | Remarks           |
|-----------------------------------|-----------|-------------------|
| <code>TABLE_CATALOG</code>        |           | <code>NULL</code> |
| <code>TABLE_SCHEMA</code>         |           |                   |
| <code>TABLE_NAME</code>           |           |                   |
| <code>VIEW_DEFINITION</code>      |           |                   |
| <code>CHECK_OPTION</code>         |           |                   |
| <code>IS_UPDATABLE</code>         |           |                   |
| <code>DEFINER</code>              |           |                   |
| <code>SECURITY_TYPE</code>        |           |                   |
| <code>CHARACTER_SET_CLIENT</code> |           | MySQL extension   |
| <code>COLLATION_CONNECTION</code> |           | MySQL extension   |

### Notes:

- The `VIEW_DEFINITION` column has most of what you see in the `Create Table` field that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
SELECT s2,s1 FROM t
WHERE s1 > 5
ORDER BY s1
WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The `CHECK_OPTION` column always has a value of `NONE`.
- MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 25.2, “CREATE VIEW Syntax”](#).)
- The `DEFINER` column indicates who defined the view. `SECURITY_TYPE` has a value of `DEFINER` or `INVOKER`.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the view was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the view was created. These columns were added in MySQL 5.1.21.

## 26.16. The INFORMATION\_SCHEMA TRIGGERS Table

The `TRIGGERS` table provides information about triggers. You must have the `TRIGGER` privilege to access this table (prior to MySQL 5.1.22, you must have the `SUPER` privilege).

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|---------|
|-------------------------|-----------|---------|

|                            |           |                 |
|----------------------------|-----------|-----------------|
| TRIGGER_CATALOG            |           | NULL            |
| TRIGGER_SCHEMA             |           |                 |
| TRIGGER_NAME               | Trigger   |                 |
| EVENT_MANIPULATION         | Event     |                 |
| EVENT_OBJECT_CATALOG       |           | NULL            |
| EVENT_OBJECT_SCHEMA        |           |                 |
| EVENT_OBJECT_TABLE         | Table     |                 |
| ACTION_ORDER               |           | 0               |
| ACTION_CONDITION           |           | NULL            |
| ACTION_STATEMENT           | Statement |                 |
| ACTION_ORIENTATION         |           | ROW             |
| ACTION_TIMING              | Timing    |                 |
| ACTION_REFERENCE_OLD_TABLE |           | NULL            |
| ACTION_REFERENCE_NEW_TABLE |           | NULL            |
| ACTION_REFERENCE_OLD_ROW   |           | OLD             |
| ACTION_REFERENCE_NEW_ROW   |           | NEW             |
| CREATED                    |           | NULL (0)        |
| SQL_MODE                   |           | MySQL extension |
| DEFINER                    |           | MySQL extension |
| CHARACTER_SET_CLIENT       |           | MySQL extension |
| COLLATION_CONNECTION       |           | MySQL extension |
| DATABASE_COLLATION         |           | MySQL extension |

**Notes:**

- The `TRIGGER_SCHEMA` and `TRIGGER_NAME` columns contain the name of the database in which the trigger occurs and the trigger name, respectively.
- The `EVENT_MANIPULATION` column contains one of the values 'INSERT', 'DELETE', or 'UPDATE'.
- As noted in [Chapter 23, Triggers](#), every trigger is associated with exactly one table. The `EVENT_OBJECT_SCHEMA` and `EVENT_OBJECT_TABLE` columns contain the database in which this table occurs, and the table's name.
- The `ACTION_ORDER` statement contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always 0, because it is not possible to have more than one trigger with the same `EVENT_MANIPULATION` and `ACTION_TIMING` on the same table.
- The `ACTION_STATEMENT` column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the `Statement` column of the output from `SHOW TRIGGERS`. Note that this text uses UTF-8 encoding.
- The `ACTION_ORIENTATION` column always contains the value 'ROW'.
- The `ACTION_TIMING` column contains one of the two values 'BEFORE' or 'AFTER'.
- The columns `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW` contain the old and new column identifiers, respectively. This means that `ACTION_REFERENCE_OLD_ROW` always contains the value 'OLD' and `ACTION_REFERENCE_NEW_ROW` always contains the value 'NEW'.
- The `SQL_MODE` column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the `sql_mode` system variable. See [Section 5.1.7, “SQL Modes”](#).
- The `DEFINER` column was added in MySQL 5.1.2. `DEFINER` indicates who defined the trigger.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the trigger was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the trigger was created. `DATABASE_COLLATION` is the collation of the database with which the trigger is associated. These columns were added in MySQL 5.1.21.

- The following columns currently always contain NULL: TRIGGER\_CATALOG, EVENT\_OBJECT\_CATALOG, ACTION\_CONDITION, ACTION\_REFERENCE\_OLD\_TABLE, ACTION\_REFERENCE\_NEW\_TABLE, and CREATED.

Example, using the `ins_sum` trigger defined in Section 23.3, “Using Triggers”:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
***** 1. row *****
 TRIGGER_CATALOG: NULL
 TRIGGER_SCHEMA: test
 TRIGGER_NAME: ins_sum
 EVENT_MANIPULATION: INSERT
 EVENT_OBJECT_CATALOG: NULL
 EVENT_OBJECT_SCHEMA: test
 EVENT_OBJECT_TABLE: account
 ACTION_ORDER: 0
 ACTION_CONDITION: NULL
 ACTION_STATEMENT: SET @sum = @sum + NEW.amount
 ACTION_ORIENTATION: ROW
 ACTION_TIMING: BEFORE
 ACTION_REFERENCE_OLD_TABLE: NULL
 ACTION_REFERENCE_NEW_TABLE: NULL
 ACTION_REFERENCE_OLD_ROW: OLD
 ACTION_REFERENCE_NEW_ROW: NEW
 CREATED: NULL
 SQL_MODE:
 DEFINER: me@localhost
```

See also Section 12.5.4.30, “SHOW TRIGGERS Syntax”.

## 26.17. The INFORMATION\_SCHEMA PLUGINS Table

The `PLUGINS` table provides information about server plugins.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks         |
|-------------------------|-----------|-----------------|
| PLUGIN_NAME             | Name      | MySQL extension |
| PLUGIN_VERSION          |           | MySQL extension |
| PLUGIN_STATUS           | Status    | MySQL extension |
| PLUGIN_TYPE             | Type      | MySQL extension |
| PLUGIN_TYPE_VERSION     |           | MySQL extension |
| PLUGIN_LIBRARY          | Library   | MySQL extension |
| PLUGIN_LIBRARY_VERSION  |           | MySQL extension |
| PLUGIN_AUTHOR           |           | MySQL extension |
| PLUGIN_DESCRIPTION      |           | MySQL extension |
| PLUGIN_LICENSE          |           | MySQL extension |

### Notes:

- The `PLUGINS` table is a non-standard table. It was added in MySQL 5.1.5.
- The `PLUGIN_LICENSE` column was added in MySQL 5.1.12.

See also Section 12.5.4.21, “SHOW PLUGINS Syntax”.

## 26.18. The INFORMATION\_SCHEMA ENGINES Table

The `PLUGINS` table provides information about storage engines.

| INFORMATION_SCHEMA Name | SHOW Name    | Remarks         |
|-------------------------|--------------|-----------------|
| ENGINE                  | Engine       | MySQL extension |
| SUPPORT                 | Support      | MySQL extension |
| COMMENT                 | Comment      | MySQL extension |
| TRANSACTIONS            | Transactions | MySQL extension |
| XA                      | XA           | MySQL extension |

|            |            |                 |
|------------|------------|-----------------|
| SAVEPOINTS | Savepoints | MySQL extension |
|------------|------------|-----------------|

**Notes:**

- The `ENGINES` table is a non-standard table. It was added in MySQL 5.1.5.

See also [Section 12.5.4.14, “SHOW ENGINES Syntax”](#).

## 26.19. The INFORMATION\_SCHEMA PARTITIONS Table

The `PARTITIONS` table provides information about table partitions. See [Chapter 20, Partitioning](#), for more information about partitioning tables.

| INFORMATION_SCHEMA Name       | SHOW Name | Remarks         |
|-------------------------------|-----------|-----------------|
| TABLE_CATALOG                 |           | MySQL extension |
| TABLE_SCHEMA                  |           | MySQL extension |
| TABLE_NAME                    |           | MySQL extension |
| PARTITION_NAME                |           | MySQL extension |
| SUBPARTITION_NAME             |           | MySQL extension |
| PARTITION_ORDINAL_POSITION    |           | MySQL extension |
| SUBPARTITION_ORDINAL_POSITION |           | MySQL extension |
| PARTITION_METHOD              |           | MySQL extension |
| SUBPARTITION_METHOD           |           | MySQL extension |
| PARTITION_EXPRESSION          |           | MySQL extension |
| SUBPARTITION_EXPRESSION       |           | MySQL extension |
| PARTITION_DESCRIPTION         |           | MySQL extension |
| TABLE_ROWS                    |           | MySQL extension |
| AVG_ROW_LENGTH                |           | MySQL extension |
| DATA_LENGTH                   |           | MySQL extension |
| MAX_DATA_LENGTH               |           | MySQL extension |
| INDEX_LENGTH                  |           | MySQL extension |
| DATA_FREE                     |           | MySQL extension |
| CREATE_TIME                   |           | MySQL extension |
| UPDATE_TIME                   |           | MySQL extension |
| CHECK_TIME                    |           | MySQL extension |
| CHECKSUM                      |           | MySQL extension |
| PARTITION_COMMENT             |           | MySQL extension |
| NODEGROUP                     |           | MySQL extension |
| TABLESPACE_NAME               |           | MySQL extension |

**Notes:**

- The `PARTITIONS` table is a non-standard table. It was added in MySQL 5.1.6.  
Each record in this table corresponds to an individual partition or subpartition of a partitioned table.
- `TABLE_CATALOG`: This column is always `NULL`.
- `TABLE_SCHEMA`: This column contains the name of the database to which the table belongs.
- `TABLE_NAME`: This column contains the name of the table containing the partition.
- `PARTITION_NAME`: The name of the partition.

- **SUBPARTITION\_NAME**: If the **PARTITIONS** table record represents a subpartition, then this column contains the name of subpartition; otherwise it is **NULL**.
- **PARTITION\_ORDINAL\_POSITION**: All partitions are indexed in the same order as they are defined, with **1** being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown in this column reflects the current order, taking into account any indexing changes.
- **SUBPARTITION\_ORDINAL\_POSITION**: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.
- **PARTITION\_METHOD**: One of the values **RANGE**, **LIST**, **HASH**, **LINEAR HASH**, **KEY**, or **LINEAR KEY**; that is, one of the available partitioning types as discussed in [Section 20.2, “Partition Types”](#).
- **SUBPARTITION\_METHOD**: One of the values **HASH**, **LINEAR HASH**, **KEY**, or **LINEAR KEY**; that is, one of the available subpartitioning types as discussed in [Section 20.2.5, “Subpartitioning”](#).
- **PARTITION\_EXPRESSION**: This is the expression for the partitioning function used in the **CREATE TABLE** or **ALTER TABLE** statement that created the table's current partitioning scheme.

For example, consider a partitioned table created in the **test** database using this statement:

```
CREATE TABLE tp (
 c1 INT,
 c2 INT,
 c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

The **PARTITION\_EXPRESSION** column in a **PARTITIONS** table record for a partition from this table displays **c1 + c2**, as shown here:

```
mysql> SELECT DISTINCT PARTITION_EXPRESSION
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2 |
+-----+
1 row in set (0.09 sec)
```

- **SUBPARTITION\_EXPRESSION**: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as **PARTITION\_EXPRESSION** does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, then this column is **NULL**.

- **PARTITION\_DESCRIPTION**: This column is used for **RANGE** and **LIST** partitions. For a **RANGE** partition, it contains the value set in the partition's **VALUES LESS THAN** clause, which can be either an integer or **MAXVALUE**. For a **LIST** partition, this column contains the values defined in the partition's **VALUES IN** clause, which is a comma-separated list of integer values.

For partitions whose **PARTITION\_METHOD** is other than **RANGE** or **LIST**, this column is always **NULL**.

- **TABLE\_ROWS**: The number of table rows in the partition.
- **AVG\_ROW\_LENGTH**: The average length of the rows stored in this partition or subpartition, in bytes.

This is the same as **DATA\_LENGTH** divided by **TABLE\_ROWS**.

- **DATA\_LENGTH**: The total length of all rows stored in this partition or subpartition, in bytes — that is, the total number of bytes stored in the partition or subpartition.
- **MAX\_DATA\_LENGTH**: The maximum number of bytes that can be stored in this partition or subpartition.
- **INDEX\_LENGTH**: The length of the index file for this partition or subpartition, in bytes.
- **DATA\_FREE**: The number of bytes allocated to the partition or subpartition but not used.
- **CREATE\_TIME**: The time of the partition's or subpartition's creation.
- **UPDATE\_TIME**: The time that the partition or subpartition was last modified.
- **CHECK\_TIME**: The last time that the table to which this partition or subpartition belongs was checked.

**Note**

Some storage engines do not update this time; for tables using these storage engines, this value is always `NULL`.

- `CHECKSUM`: The checksum value, if any; otherwise, this column is `NULL`.
- `PARTITION_COMMENT`: This column contains the text of any comment made for the partition.

The default value for this column is an empty string.

- `NODEGROUP`: This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always `0`.
- `TABLESPACE_NAME`: This column contains the name of tablespace to which the partition belongs. In MySQL 5.1, the value of this column is always `DEFAULT`.

**Important**

If any partitioned tables created in a MySQL version prior to MySQL 5.1.6 are present following an upgrade to MySQL 5.1.6 or later, it is not possible to `SELECT` from, `SHOW`, or `DESCRIBE` the `PARTITIONS` table. See [Section C.1.22, “Changes in MySQL 5.1.6 \(01 February 2006\)”](#) before upgrading from MySQL 5.1.5 or earlier to MySQL 5.1.6 or later.

- A non-partitioned table has one record in `INFORMATION_SCHEMA.PARTITIONS`; however, the values of the `PARTITION_NAME`, `SUBPARTITION_NAME`, `PARTITION_ORDINAL_POSITION`, `SUBPARTITION_ORDINAL_POSITION`, `PARTITION_METHOD`, `SUBPARTITION_METHOD`, `PARTITION_EXPRESSION`, `SUBPARTITION_EXPRESSION`, and `PARTITION_DESCRIPTION` columns are all `NULL`. (The `PARTITION_COMMENT` column in this case is blank.)

In MySQL 5.1, there is also only one record in the `PARTITIONS` table for a table using the `NDBCLUSTER` storage engine. The same columns are also `NULL` (or empty) as for a non-partitioned table.

## 26.20. The `INFORMATION_SCHEMA.EVENTS` Table

The `EVENTS` table provides information about scheduled events, which are discussed in [Chapter 24, Event Scheduler](#).

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name      | Remarks                             |
|--------------------------------------|-----------------------------|-------------------------------------|
| <code>EVENT_CATALOG</code>           |                             | <code>NULL</code> , MySQL extension |
| <code>EVENT_SCHEMA</code>            | <code>Db</code>             | MySQL extension                     |
| <code>EVENT_NAME</code>              | <code>Name</code>           | MySQL extension                     |
| <code>DEFINER</code>                 | <code>Definer</code>        | MySQL extension                     |
| <code>TIME_ZONE</code>               | <code>Time zone</code>      | MySQL extension                     |
| <code>EVENT_BODY</code>              |                             | MySQL extension                     |
| <code>EVENT_DEFINITION</code>        |                             | MySQL extension                     |
| <code>EVENT_TYPE</code>              | <code>Type</code>           | MySQL extension                     |
| <code>EXECUTE_AT</code>              | <code>Execute at</code>     | MySQL extension                     |
| <code>INTERVAL_VALUE</code>          | <code>Interval value</code> | MySQL extension                     |
| <code>INTERVAL_FIELD</code>          | <code>Interval field</code> | MySQL extension                     |
| <code>SQL_MODE</code>                |                             | MySQL extension                     |
| <code>STARTS</code>                  | <code>Starts</code>         | MySQL extension                     |
| <code>ENDS</code>                    | <code>Ends</code>           | MySQL extension                     |
| <code>STATUS</code>                  | <code>Status</code>         | MySQL extension                     |
| <code>ON_COMPLETION</code>           |                             | MySQL extension                     |
| <code>CREATED</code>                 |                             | MySQL extension                     |
| <code>LAST_ALTERED</code>            |                             | MySQL extension                     |
| <code>LAST_EXECUTED</code>           |                             | MySQL extension                     |
| <code>EVENT_COMMENT</code>           |                             | MySQL extension                     |
| <code>ORIGINATOR</code>              | <code>Originator</code>     | MySQL extension                     |

|                      |  |                 |
|----------------------|--|-----------------|
| CHARACTER_SET_CLIENT |  | MySQL extension |
| COLLATION_CONNECTION |  | MySQL extension |
| DATABASE_COLLATION   |  | MySQL extension |

**Notes:**

- The `EVENTS` table is a non-standard table. It was added in MySQL 5.1.6.
- `EVENT_CATALOG`: The value of this column is always `NULL`.
- `EVENT_SCHEMA`: The name of the schema (database) to which this event belongs.
- `EVENT_NAME`: The name of the event.
- `DEFINER`: The user who created the event. Always displayed in '`user_name`'@'`host_name`' format.
- `TIME_ZONE`: The time zone in effect when schedule for the event was last modified. If the event's schedule has not been modified since the event was created, then this is the time zone that was in effect at the event's creation. The default value is `SYSTEM`.

This column was added in MySQL 5.1.17. See [Section C.1.11, "Changes in MySQL 5.1.17 \(04 April 2007\)"](#), for important information if you are using the Event Scheduler and are upgrading from MySQL 5.1.16 (or earlier) to MySQL 5.1.17 (or later).

- `EVENT_BODY`: The language used for the statements in the event's `DO` clause; in MySQL 5.1, this is always `SQL`.

This column was added in MySQL 5.1.12. It is not to be confused with the column of the same name (now named `EVENT_DEFINITION`) that existed in earlier MySQL versions.

- `EVENT_DEFINITION`: The text of the SQL statement making up the event's `DO` clause; in other words, the statement executed by this event.

**Note**

Prior to MySQL 5.1.12, this column was named `EVENT_BODY`.

- `EVENT_TYPE`: One of the two values `ONE TIME` or `RECURRING`.
- `EXECUTE_AT`: For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be '`2006-02-10 20:05:30`'.

If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.

- `INTERVAL_VALUE`: For recurring events, this column contains the numeric portion of the event's `EVERY` clause.

For a one-time event (that is, an event whose timing is determined by an `AT` clause), this column's value is `NULL`.

- `INTERVAL_FIELD`: For recurring events, this column contains the units portion of the `EVERY` clause governing the timing of the event, prefixed with '`INTERVAL_`'. Thus, this column contains a value such as '`INTERVAL_YEAR`', '`INTERVAL_QUARTER`', '`INTERVAL_DAY`', and so on.

For a one-time event (that is, an event whose timing is determined by an `AT` clause), this column's value is `NULL`.

- `SQL_MODE`: The SQL mode in effect at the time the event was created or altered.
- `STARTS`: For a recurring event whose definition includes a `STARTS` clause, this column contains the corresponding `DATE-TIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used.

If there is no `STARTS` clause affecting the timing of the event, this column is empty. (Prior to MySQL 5.1.8, it contained `NULL` in such cases.)

- `ENDS`: For a recurring event whose definition includes a `ENDS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column (see previous example), this value resolves any expressions used.

If there is no `ENDS` clause affecting the timing of the event, this column contains `NULL`.

- **STATUS:** One of the three values `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.

`SLAVESIDE_DISABLED` was added to the list of possible values for this column in MySQL 5.1.18. This value indicates that the creation of the event occurred on another MySQL server acting as a replication master and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See [Section 18.3.1.5, “Replication of Invoked Features”](#), for more information.

- **ON\_COMPLETION:** One of the two values `PRESERVE` or `NOT PRESERVE`.
- **CREATED:** The date and time when the event was created. This is a `DATETIME` value.
- **LAST\_ALTERED:** The date and time when the event was last modified. This is a `DATETIME` value. If the event has not been modified since its creation, this column holds the same value as the `CREATED` column.
- **LAST\_EXECUTED:** The date and time when the event last executed. A `DATETIME` value. If the event has never executed, this column's value is `NULL`.

Before MySQL 5.1.23, `LAST_EXECUTED` indicates when event finished executing. As of 5.1.23, `LAST_EXECUTED` instead indicates when the event started. As a result, the `ENDS` column is never less than `LAST_EXECUTED`.

- **EVENT\_COMMENT:** The text of a comment, if the event has one. If there is no comment, the value of this column is an empty string.
- **ORIGINATOR:** The server ID of the MySQL server on which the event was created; used in replication. The default value is 0. This column was added in MySQL 5.1.18.
- **CHARACTER\_SET\_CLIENT** is the session value of the `character_set_client` system variable when the event was created. **COLLATION\_CONNECTION** is the session value of the `collation_connection` system variable when the event was created. **DATABASE\_COLLATION** is the collation of the database with which the event is associated. These columns were added in MySQL 5.1.21.

**Example:** Suppose the user `jon@ghidora` creates an event named `e_daily`, and then modifies it a few minutes later using an `ALTER EVENT` statement, as shown here:

```
DELIMITER |
CREATE EVENT e_daily
ON SCHEDULE EVERY 1 DAY
STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
DISABLE
COMMENT 'Saves total number of sessions and
clears the table once per day.'
DO
BEGIN
INSERT INTO site_activity.totals (when, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END |
DELIMITER ;
ALTER EVENT e_daily
ENABLED;
```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME = 'e_daily'
> AND EVENT_SCHEMA = 'myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_daily
DEFINER: jon@ghidora
EVENT_BODY: BEGIN
 INSERT INTO site_activity.totals (when, total)
 SELECT CURRENT_TIMESTAMP, COUNT(*)
 FROM site_activity.sessions;
 DELETE FROM site_activity.sessions;
 END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: INTERVAL_DAY
SQL_MODE: NULL
STARTS: 2006-02-09 10:41:23
ENDS: NULL
```

```

STATUS: ENABLED
ON_COMPLETION: DROP
CREATED: 2006-02-09 14:35:35
LAST_ALTERED: 2006-02-09 14:41:23
LAST_EXECUTED: NULL
EVENT_COMMENT: Saves total number of sessions and
clears the table once per day.
ORIGINATOR: 0
1 row in set (0.50 sec)

```

Prior to MySQL 5.1.17, the times displayed in the `STARTS`, `ENDS`, and `LAST_EXECUTED` columns were given in terms of Universal Time (GMT or UTC), regardless of the server's time zone setting ([Bug#16420](#)). Beginning with MySQL 5.1.17, these times are all given in terms of local time as determined by the MySQL server's `time_zone` setting. (The same was true of the `starts`, `ends`, and `last_executed` columns of the `mysql.event` table as well as the `Starts` and `Ends` columns in the output of `SHOW [FULL] EVENTS`.)

The `CREATED` and `LAST_ALTERED` columns use the server time zone (as do the `created` and `last_altered` columns of the `mysql.event` table).

See also [Section 12.5.4.16](#), "SHOW EVENTS".

## 26.21. The INFORMATION\_SCHEMA FILES Table

The `FILES` table provides information about the files in which MySQL NDB Disk Data tables are stored.

| INFORMATION_SCHEMA Name           | SHOW Name | Remarks         |
|-----------------------------------|-----------|-----------------|
| <code>FILE_ID</code>              |           | MySQL extension |
| <code>FILE_NAME</code>            |           | MySQL extension |
| <code>FILE_TYPE</code>            |           | MySQL extension |
| <code>TABLESPACE_NAME</code>      |           | MySQL extension |
| <code>TABLE_CATALOG</code>        |           | MySQL extension |
| <code>TABLE_SCHEMA</code>         |           | MySQL extension |
| <code>TABLE_NAME</code>           |           | MySQL extension |
| <code>LOGFILE_GROUP_NAME</code>   |           | MySQL extension |
| <code>LOGFILE_GROUP_NUMBER</code> |           | MySQL extension |
| <code>ENGINE</code>               |           | MySQL extension |
| <code>FULLTEXT_KEYS</code>        |           | MySQL extension |
| <code>DELETED_ROWS</code>         |           | MySQL extension |
| <code>UPDATE_COUNT</code>         |           | MySQL extension |
| <code>FREE_EXTENTS</code>         |           | MySQL extension |
| <code>TOTAL_EXTENTS</code>        |           | MySQL extension |
| <code>EXTENT_SIZE</code>          |           | MySQL extension |
| <code>INITIAL_SIZE</code>         |           | MySQL extension |
| <code>MAXIMUM_SIZE</code>         |           | MySQL extension |
| <code>AUTOEXTEND_SIZE</code>      |           | MySQL extension |
| <code>CREATION_TIME</code>        |           | MySQL extension |
| <code>LAST_UPDATE_TIME</code>     |           | MySQL extension |
| <code>LAST_ACCESS_TIME</code>     |           | MySQL extension |
| <code>RECOVER_TIME</code>         |           | MySQL extension |
| <code>TRANSACTION_COUNTER</code>  |           | MySQL extension |
| <code>VERSION</code>              |           | MySQL extension |
| <code>ROW_FORMAT</code>           |           | MySQL extension |
| <code>TABLE_ROWS</code>           |           | MySQL extension |
| <code>AVG_ROW_LENGTH</code>       |           | MySQL extension |
| <code>DATA_LENGTH</code>          |           | MySQL extension |
| <code>MAX_DATA_LENGTH</code>      |           | MySQL extension |
| <code>INDEX_LENGTH</code>         |           | MySQL extension |

|             |  |                 |
|-------------|--|-----------------|
| DATA_FREE   |  | MySQL extension |
| CREATE_TIME |  | MySQL extension |
| UPDATE_TIME |  | MySQL extension |
| CHECK_TIME  |  | MySQL extension |
| CHECKSUM    |  | MySQL extension |
| STATUS      |  | MySQL extension |
| EXTRA       |  | MySQL extension |

**Notes:**

- `FILE_ID` column values are auto-generated.
- `FILE_NAME` is the name of an `UNDO` log file created by `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP`, or of a data file created by `CREATE TABLESPACE` or `ALTER TABLESPACE`.
- `FILE_TYPE` is one of the values `UNDOFILE` or `DATAFILE`.
- `TABLESPACE_NAME` is the name of the tablespace with which the file is associated.
- In MySQL 5.1, the value of the `TABLESPACE_CATALOG` column is always `NULL`.
- `TABLE_NAME` is the name of the Disk Data table with which the file is associated, if any.
- The `LOGFILE_GROUP_NAME` column gives the name of the log file group to which the log file or data file belongs.
- For an `UNDO` log file, the `LOGFILE_GROUP_NUMBER` contains the auto-generated ID number of the log file group to which the log file belongs.
- For a MySQL Cluster Disk Data log file or data file, the value of the `ENGINE` column is always `NDB` or `NDBCLUSTER`.
- For a MySQL Cluster Disk Data log file or data file, the value of the `FULLTEXT_KEYS` column is always empty.
- The `FREE_EXTENTS` column displays the number of extents which have not yet been used by the file. The `TOTAL_EXTENTS` column show the total number of extents allocated to the file.

The difference between these two columns is the number of extents currently in use by the file:

```
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

You can approximate the amount of disk space in use by the file by multiplying this difference by the value of the `EXTENT_SIZE` column, which gives the size of an extent for the file in bytes:

```
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying `FREE_EXTENTS` by `EXTENT_SIZE`:

```
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

**Important**

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of `EXTENT_SIZE`. That is, the larger `EXTENT_SIZE` becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do *not* release disk space.

The extent size can be set in a `CREATE TABLESPACE` statement. See [Section 12.1.11, “CREATE TABLESPACE Syntax”](#), for more information.

- The `INITIAL_SIZE` column shows the size in bytes of the file. This is the same value that was used in the `INITIAL_SIZE` clause of the `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, or `ALTER TABLESPACE` statement used to create the file.

For MySQL 5.1 Cluster Disk Data files, the value of the `MAXIMUM_SIZE` column is always the same as `INITIAL_SIZE`, and the `AUTOEXTEND_SIZE` column is always empty.

- The `CREATION_TIME` column shows the date and time when the file was created. The `LAST_UPDATE_TIME` column displays the date and time when the file was last modified. The `LAST_ACCESSED` column provides the date and time when the file was last accessed by the server.

Currently, the values of these columns are as reported by the operating system, and are not supplied by the `NDB` storage engine. Where no value is provided by the operating system, these columns display `0000-00-00 00:00:00`.

- For MySQL Cluster Disk Data files, the value of the `RECOVER_TIME` and `TRANSACTION_COUNTER` columns is always 0.
- For MySQL 5.1 Cluster Disk Data files, the following columns are always `NULL`:

- `VERSION`
- `ROW_FORMAT`
- `TABLE_ROWS`
- `AVG_ROW_LENGTH`
- `DATA_LENGTH`
- `MAX_DATA_LENGTH`
- `INDEX_LENGTH`
- `DATA_FREE`
- `CREATE_TIME`
- `UPDATE_TIME`
- `CHECK_TIME`
- `CHECKSUM`

- For MySQL Cluster Disk Data files, the value of the `STATUS` column is always `NORMAL`.
- For MySQL Cluster Disk Data files, the `EXTRA` column shows which data node the file belongs to, as each data node has its own copy of the file. For example, suppose you use this statement on a MySQL Cluster with four data nodes:

```
CREATE LOGFILE GROUP mygroup
ADD UNDOFILE 'new_undo.dat'
INITIAL_SIZE 2G
ENGINE NDB;
```

After running the `CREATE LOGFILE GROUP` statement successfully, you should see a result similar to the one shown here for this query against the `FILES` table:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME = 'new_undo.dat';
```

| LOGFILE_GROUP_NAME | FILE_TYPE | EXTRA          |
|--------------------|-----------|----------------|
| mygroup            | UNDO FILE | CLUSTER_NODE=3 |
| mygroup            | UNDO FILE | CLUSTER_NODE=4 |
| mygroup            | UNDO FILE | CLUSTER_NODE=5 |
| mygroup            | UNDO FILE | CLUSTER_NODE=6 |

4 rows in set (0.01 sec)

- The `FILES` table is a non-standard table. It was added in MySQL 5.1.6.
- Beginning with MySQL 5.1.14, an additional row is present in the `FILES` table following the creation of a logfile group. This row has `NULL` for the value of the `FILE_NAME` column. For this row, the value of the `FILE_ID` column is always 0, that of the `FILE_TYPE` column is always `UNDO FILE`, and that of the `STATUS` column is always `NORMAL`. In MySQL 5.1 the value of the `ENGINE` column is always `ndbcluster`.

This row shows in the `FREE_EXTENTS` column the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the `LOGFILE_GROUP_NAME` and `LOGFILE_GROUP_NUMBER` columns, respectively.

Suppose there are no existing log file groups on your MySQL Cluster, and you create one using the following statement:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile.dat'
-> INITIAL_SIZE = 16M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE = NDB;
Query OK, 0 rows affected (3.81 sec)
```

You can now see this `NULL` row when you query the `FILES` table:

```
mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS Size,
-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
```

| File         | Free    | Total   | Size | Initial  |
|--------------|---------|---------|------|----------|
| undofile.dat | NULL    | 4194304 | 4    | 16777216 |
| NULL         | 4184068 | NULL    | 4    | NULL     |

2 rows in set (0.01 sec)

The total number of free extents available for undo logging is always somewhat less than the sum of the `TOTAL_EXTENTS` column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the `FILES` table:

```
mysql> ALTER LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile02.dat'
-> INITIAL_SIZE = 4M
-> ENGINE = NDB;
Query OK, 0 rows affected (1.02 sec)
```

```
mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS Size,
-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
```

| File           | Free    | Total   | Size | Initial  |
|----------------|---------|---------|------|----------|
| undofile.dat   | NULL    | 4194304 | 4    | 16777216 |
| undofile02.dat | NULL    | 1048576 | 4    | 4194304  |
| NULL           | 5223944 | NULL    | 4    | NULL     |

3 rows in set (0.01 sec)

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```
mysql> SELECT
-> FREE_EXTENTS AS 'Free Extents',
-> FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
```

| Free Extents | Free Bytes |
|--------------|------------|
| 5223944      | 20895776   |

1 row in set (0.02 sec)

If you create a Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterwards, for example:

```
mysql> CREATE TABLESPACE ts1
-> ADD DATAFILE 'data1.dat'
-> USE LOGFILE GROUP lg1
-> INITIAL_SIZE 512M
-> ENGINE = NDB;
Query OK, 0 rows affected (8.71 sec)
```

```
mysql> CREATE TABLE dd (
-> c1 INT NOT NULL PRIMARY KEY,
```

```

-> c2 INT,
-> c3 DATE
->)
-> TABLESPACE ts1 STORAGE DISK
-> ENGINE = NDB;
Query OK, 0 rows affected (2.11 sec)

mysql> INSERT INTO dd VALUES
-> (NULL, 1234567890, '2007-02-02'),
-> (NULL, 1126789005, '2007-02-03'),
-> (NULL, 1357924680, '2007-02-04'),
-> (NULL, 1642097531, '2007-02-05');
Query OK, 4 rows affected (0.01 sec)

mysql> SELECT
-> FREE_EXTENTS AS 'Free Extents',
-> FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
| 5207565 | 20830260 |
+-----+-----+
1 row in set (0.01 sec)

```

- There are no `SHOW` commands associated with the `FILES` table.
- For additional examples using the `FILES` table to obtain information about Cluster Disk Data tables, see [Section 19.12](#), “MySQL Cluster Disk Data Tables”.

## 26.22. The INFORMATION\_SCHEMA PROCESSLIST Table

The `PROCESSLIST` table provides information about which threads are running.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks         |
|-------------------------|-----------|-----------------|
| ID                      | Id        | MySQL extension |
| USER                    | User      | MySQL extension |
| HOST                    | Host      | MySQL extension |
| DB                      | db        | MySQL extension |
| COMMAND                 | Command   | MySQL extension |
| TIME                    | Time      | MySQL extension |
| STATE                   | State     | MySQL extension |
| INFO                    | Info      | MySQL extension |

For an extensive description of the table columns, see [Section 12.5.4.25](#), “`SHOW PROCESSLIST` Syntax”.

### Notes:

- The `PROCESSLIST` table is a non-standard table. It was added in MySQL 5.1.7.
- Like the output from the corresponding `SHOW` statement, the `PROCESSLIST` table will only show information about your own threads, unless you have the `PROCESS` privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.
- If an SQL statement refers to `INFORMATION_SCHEMA.PROCESSLIST`, then MySQL will populate the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.

The following statements are equivalent:

```

SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW FULL PROCESSLIST

```

## 26.23. The INFORMATION\_SCHEMA REFERENTIAL\_CONSTRAINTS Ta-

## ble

The `REFERENTIAL_CONSTRAINTS` table provides information about foreign keys.

| INFORMATION_SCHEMA Name   | SHOW Name | Remarks |
|---------------------------|-----------|---------|
| CONSTRAINT_CATALOG        |           | NULL    |
| CONSTRAINT_SCHEMA         |           |         |
| CONSTRAINT_NAME           |           |         |
| UNIQUE_CONSTRAINT_CATALOG |           | NULL    |
| UNIQUE_CONSTRAINT_SCHEMA  |           |         |
| UNIQUE_CONSTRAINT_NAME    |           |         |
| MATCH_OPTION              |           |         |
| UPDATE_RULE               |           |         |
| DELETE_RULE               |           |         |
| TABLE_NAME                |           |         |
| REFERENCED_TABLE_NAME     |           |         |

### Notes:

- The `REFERENTIAL_CONSTRAINTS` table was added in MySQL 5.1.10. The `REFERENCED_TABLE_NAME` column was added in MySQL 5.1.16.
- `TABLE_NAME` has the same value as `TABLE_NAME` in `INFORMATION_SCHEMA.TABLE_CONSTRAINTS`.
- `CONSTRAINT_SCHEMA` and `CONSTRAINT_NAME` identify the foreign key.
- `UNIQUE_CONSTRAINT_SCHEMA`, `UNIQUE_CONSTRAINT_NAME`, and `REFERENCED_TABLE_NAME` identify the referenced key. (Note: Before MySQL 5.1.16, `UNIQUE_CONSTRAINT_NAME` incorrectly named the referenced table, not the constraint.)
- The only valid value at this time for `MATCH_OPTION` is `NONE`.
- The possible values for `UPDATE_RULE` or `DELETE_RULE` are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

## 26.24. The INFORMATION\_SCHEMA GLOBAL\_STATUS and SESSION\_STATUS Tables

The `GLOBAL_STATUS` and `SESSION_STATUS` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL STATUS` and `SHOW SESSION STATUS` statements (see [Section 12.5.4.27](#), “`SHOW STATUS Syntax`”).

| INFORMATION_SCHEMA Name | SHOW Name     | Remarks |
|-------------------------|---------------|---------|
| VARIABLE_NAME           | Variable_name |         |
| VARIABLE_VALUE          | Value         |         |

### Notes:

- The `GLOBAL_STATUS` and `SESSION_STATUS` tables were added in MySQL 5.1.12.
- Beginning with MySQL 5.1.19, the `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`. Previously, this column had the data type `DECIMAL(22,7)`, but was changed to avoid loss of data when working with status variables whose values were strings ([Bug#26994](#)).

## 26.25. The INFORMATION\_SCHEMA GLOBAL\_VARIABLES and SES-

## SION\_VARIABLES Tables

The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL VARIABLES` and `SHOW SESSION VARIABLES` statements (see [Section 12.5.4.31](#), “`SHOW VARIABLES Syntax`”).

| INFORMATION_SCHEMA Name | SHOW Name     | Remarks |
|-------------------------|---------------|---------|
| VARIABLE_NAME           | Variable_name |         |
| VARIABLE_VALUE          | Value         |         |

### Notes:

- The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables were added in MySQL 5.1.12.
- Beginning with MySQL 5.1.19, the `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`. Previously, this column had the data type `LONGTEXT`; this was changed in order to make these tables consistent with the `GLOBAL_STATUS` and `SESSION_STATUS` tables, whose definitions had been changed in that version (see [Section 26.24](#), “[The INFORMATION\\_SCHEMA GLOBAL\\_STATUS and SESSION\\_STATUS Tables](#)”).

## 26.26. Other INFORMATION\_SCHEMA Tables

We intend to implement additional `INFORMATION_SCHEMA` tables. In particular, we acknowledge the need for the `PARAMETERS` table. (`PARAMETERS` is implemented in MySQL 6.0.)

## 26.27. Extensions to SHOW Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_INFORMATION_SCHEMA |
+-----+
| CHARACTER_SETS |
| COLLATIONS |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS |
| COLUMN_PRIVILEGES |
| ENGINES |
| EVENTS |
| FILES |
| GLOBAL_STATUS |
| GLOBAL_VARIABLES |
| KEY_COLUMN_USAGE |
| PARTITIONS |
| PLUGINS |
| PROCESSLIST |
| REFERENTIAL_CONSTRAINTS |
| ROUTINES |
| SCHEMATA |
| SCHEMA_PRIVILEGES |
| SESSION_STATUS |
| SESSION_VARIABLES |
| STATISTICS |
| TABLES |
| TABLE_CONSTRAINTS |
| TABLE_PRIVILEGES |
| TRIGGERS |
| USER_PRIVILEGES |
| VIEWS |
+-----+
27 rows in set (0.00 sec)
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE` clause to limit the rows displayed also allow a `WHERE` clause that enables specification of more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES
```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
big5	Big5 Traditional Chinese	big5_chinese_ci	2
dec8	DEC West European	dec8_swedish_ci	1
cp850	DOS West European	cp850_general_ci	1
hp8	HP West European	hp8_english_ci	1
koi8r	KOI8-R Relcom Russian	koi8r_general_ci	1
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
...			
```

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string `'japanese'`:

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3
+-----+-----+-----+-----+
```

This statement displays the multi-byte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
big5	Big5 Traditional Chinese	big5_chinese_ci	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
euckr	EUC-KR Korean	euckr_korean_ci	2
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
utf8	UTF-8 Unicode	utf8_general_ci	3
ucs2	UCS-2 Unicode	ucs2_general_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3
+-----+-----+-----+-----+
```

---

## Chapter 27. Precision Math

MySQL 5.1 provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations:

- **Precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, a number such as `.0001` is treated as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that merely “close” to `1`.
- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND( )` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the `sql_mode` system variable.

An important result of these features is that MySQL 5.1 provides a high degree of compliance with standard SQL.

The following discussion covers several aspects of how precision math works (including possible incompatibilities with older applications). At the end, some examples are given that demonstrate how MySQL 5.1 handles numeric operations precisely. For information about using the `sql_mode` system variable to control the SQL mode, see [Section 5.1.7, “SQL Modes”](#).

### 27.1. Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (`DECIMAL` and integer types) and exact-value numeric literals. Approximate-value data types and numeric literals still are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar need not be both exact-value or both approximate-value. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

### 27.2. `DECIMAL` Data Type Changes

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms) in MySQL 5.1, with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The non-standard MySQL extension to the upper range of `DECIMAL` columns

Possible incompatibilities with applications that are written for older versions of MySQL are noted throughout this section.

The declaration syntax for a `DECIMAL` column is `DECIMAL(M,D)`. The ranges of values for the arguments in MySQL 5.1 are as follows:

- *M* is the maximum number of digits (the precision). It has a range of 1 to 65. (Older versions of MySQL allowed a range of 1 to 254.)
- *D* is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than *M*.

The maximum value of 65 for *M* means that calculations on `DECIMAL` values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals is different from before. (In older versions of MySQL, decimal values could have up to 254 digits. However, calculations were done using floating-point and thus were approximate, not exact.)

Values for `DECIMAL` columns in MySQL 5.1 are stored using a binary format that packs nine decimal digits into four bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and any digits left over require some fraction of four bytes. For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require four bytes. A `DECIMAL(20,10)` column has ten digits on either side of the decimal point. Each part requires four bytes for nine of the digits, and one byte for the remaining digit.

The storage required for leftover digits is given by the following table:

| Leftover Digits | Number of Bytes |
|-----------------|-----------------|
| 0               | 0               |
| 1               | 1               |
| 2               | 1               |
| 3               | 2               |
| 4               | 2               |
| 5               | 3               |
| 6               | 3               |
| 7               | 4               |
| 8               | 4               |
| 9               | 4               |

Unlike some older versions of MySQL (prior to 5.0.3), `DECIMAL` columns in MySQL 5.1 do not store a leading `+` character or `-` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `-` character is not stored. Applications that rely on the older behavior must be modified to account for this change.

`DECIMAL` columns in MySQL 5.1 do not allow values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(M,D)` column allows at most *M* - *D* digits to the left of the decimal point. This is not compatible with applications relying on older versions of MySQL that allowed storing an extra digit in lieu of a `+` sign.

The SQL standard requires that the precision of `NUMERIC(M,D)` be *exactly* *M* digits. For `DECIMAL(M,D)`, the standard requires a precision of at least *M* digits but allows more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly *M* digits.

For more detailed information about porting applications that rely on the old treatment of the `DECIMAL` data type, see the *MySQL 5.0 Reference Manual*.

## 27.3. Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (Without strict mode, truncation for `INSERT` is allowable.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. (The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.)
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See [Section 5.1.7, “SQL Modes”](#).) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
mysql> SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it is inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in [Section 27.4, “Rounding Behavior”](#).

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

By default, division by zero produces a result of `NULL` and no warning. With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes:

| <code>sql_mode</code> Value                     | Result                                                             |
|-------------------------------------------------|--------------------------------------------------------------------|
| ' ' (Default)                                   | No warning, no error; <code>i</code> is set to <code>NULL</code> . |
| strict                                          | No warning, no error; <code>i</code> is set to <code>NULL</code> . |
| <code>ERROR_FOR_DIVISION_BY_ZERO</code>         | Warning, no error; <code>i</code> is set to <code>NULL</code> .    |
| strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code> | Error condition; no row is inserted.                               |

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has non-numeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning other-

wise. This includes the empty string.

- A string that begins with a number can be converted, but the trailing non-numeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

## 27.4. Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3 | 2 |
+-----+-----+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half up,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SELECT d FROM t;
+-----+
| d |
+-----+
| 3 |
| 3 |
+-----+
```

## 27.5. Precision Math Examples

This section provides some examples that show precision math query results in MySQL 5.1.

**Example 1.** Numbers are used with their exact value as given when possible:

```
mysql> SELECT .1 + .2 = .3;
+-----+
| .1 + .2 = .3 |
+-----+
| 1 |
+-----+
```

For floating-point values, results are inexact:

```
mysql> SELECT .1E0 + .2E0 = .3E0;
+-----+
| .1E0 + .2E0 = .3E0 |
+-----+
| 0 |
+-----+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```
CREATE PROCEDURE p ()
BEGIN
```

```

DECLARE i INT DEFAULT 0;
DECLARE d DECIMAL(10,4) DEFAULT 0;
DECLARE f FLOAT DEFAULT 0;
WHILE i < 10000 DO
 SET d = d + .0001;
 SET f = f + .0001E0;
 SET i = i + 1;
END WHILE;
SELECT d, f;
END;

```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```

+-----+-----+
| d | f |
+-----+-----+
| 1.0000 | 0.999999999999991 |
+-----+-----+

```

**Example 2.** Multiplication is performed with the scale required by standard SQL. That is, for two numbers `X1` and `X2` that have scale `S1` and `S2`, the scale of the result is `S1 + S2`:

```

mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001 |
+-----+

```

**Example 3.** Rounding behavior is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half up” rule. Values with a fractional part of .5 or greater are rounded away from zero to the nearest integer, as shown here:

```

mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+-----+
| 3 | -3 |
+-----+-----+

```

However, rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. Values with any fractional part on such systems are rounded to the nearest even integer:

```

mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+-----+
| 2 | -2 |
+-----+-----+

```

**Example 4.** In strict mode, inserting a value that is too large results in overflow and causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i |
+-----+
| 127 |
+-----+
1 row in set (0.00 sec)

```

However, an overflow condition occurs if strict mode is in effect:

```

mysql> SET sql_mode='STRICT_ALL_TABLES';

```

```

Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)

```

**Example 5:** In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, and not a result of `NULL`.

In non-strict mode, division by zero has a result of `NULL`:

```

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i |
+-----+
| NULL |
+-----+
1 row in set (0.03 sec)

```

However, division by zero is an error if the proper SQL modes are in effect:

```

mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)

```

**Example 6.** Prior to MySQL 5.0.3 (before precision math was introduced), exact-value and approximate-value literals both are converted to double-precision floating-point values:

```

mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 4.1.18-log |
+-----+
1 row in set (0.01 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.07 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a | double(3,1) | | | 0.0 | |
| b | double | | | 0 | |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.04 sec)

```

As of MySQL 5.0.3, the approximate-value literal still is converted to floating-point, but the exact-value literal is handled as `DECIMAL`:

```

mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 5.1.6-alpha-log |
+-----+
1 row in set (0.11 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+

```

| Field | Type                  | Null | Key | Default | Extra |
|-------|-----------------------|------|-----|---------|-------|
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b     | double                | NO   |     | 0       |       |

2 rows in set (0.01 sec)

**Example 7.** If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

Result before MySQL 5.0.3 (prior to the introduction of precision math in MySQL):

```
mysql> DESCRIBE y;
```

| Field  | Type         | Null | Key | Default | Extra |
|--------|--------------|------|-----|---------|-------|
| AVG(i) | double(17,4) | YES  |     | NULL    |       |
| AVG(d) | double(17,4) | YES  |     | NULL    |       |
| AVG(f) | double       | YES  |     | NULL    |       |

The result is a double no matter the argument type.

Result as of MySQL 5.0.3:

```
mysql> DESCRIBE y;
```

| Field  | Type          | Null | Key | Default | Extra |
|--------|---------------|------|-----|---------|-------|
| AVG(i) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(d) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(f) | double        | YES  |     | NULL    |       |

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

---

## Chapter 28. APIs and Libraries

This chapter describes the APIs available for MySQL, where to get them, and how to use them. The C API is the most extensively covered, because it was developed by the MySQL team, and is the basis for most of the other APIs. This chapter also covers the `libmysqld` library (the embedded server).

### 28.1. libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change an old threaded application to use the embedded library, you normally only have to add calls to the following functions:

| Function                          | When to Call                                                                                                      |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>mysql_library_init()</code> | Should be called before any other MySQL function is called, preferably early in the <code>main()</code> function. |
| <code>mysql_library_end()</code>  | Should be called before your program exits.                                                                       |
| <code>mysql_thread_init()</code>  | Should be called in each thread you create that accesses MySQL.                                                   |
| <code>mysql_thread_end()</code>   | Should be called before calling <code>pthread_exit()</code>                                                       |

Then you must link your code with `libmysqld.a` instead of `libmysqlclient.a`. To ensure binary compatibility between your application and the server library, be sure to compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if `libmysqld` was compiled against MySQL 4.1 headers, do not compile your application against MySQL 5.1 headers, or vice versa.

The `mysql_library_xxx()` functions are also included in `libmysqlclient.a` to allow you to change between the embedded and the client/server version by just linking your application with the right library. See [Section 28.2.3.40](#), “`mysql_library_init()`”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default. To use authentication for the embedded server, specify the `-with-embedded-privilege-control` option when you invoke `configure` to configure your MySQL distribution.

#### 28.1.1. Compiling Programs with `libmysqld`

In precompiled binary MySQL distributions that include `libmysqld`, the embedded server library, MySQL builds the library using the appropriate vendor compiler if there is one.

To get a `libmysqld` library if you build MySQL from source yourself, you should configure MySQL with the `-with-embedded-server` option. See [Section 2.9.2](#), “Typical configure Options”.

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into an executable version of a program, the compiler will need to know where to find various files and need instructions on how to compile the program. The following example shows how a program could be compiled from the command line, assuming that you are using `gcc`, use the GNU C compiler:

```
gcc mysql_test.c -o mysql_test -lz \
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Immediately following the `gcc` command is the name of the C program source file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it's compiled. Because of a problem with `mysql_config`, the option `-lz` (for compression) is added here. The `mysql_config` command is contained in backticks, not single quotes.

On some non-`gcc` platforms, the embedded library depends on C++ runtime libraries and linking against the embedded library might result in missing-symbol errors. To solve this, link using a C++ compiler or explicitly list the required libraries on the link command line.

## 28.1.2. Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No user-defined functions (UDFs).
- No stack trace on core dump.
- You cannot set this up as a master or a slave (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.
- `InnoDB` is not reentrant in the embedded server and cannot be used for multiple connections, either successively or simultaneously.
- The Event Scheduler is not available. Because of this, the `event_scheduler` system variable is disabled.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

## 28.1.3. Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_library_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` option as one of the elements of the second argument of the `mysql_library_init()` function. See [Section 28.2.3.40](#), “`mysql_library_init()`”, for more information on the `mysql_library_init()` function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the `[server]` group. These are read by both MySQL versions. Client/server-specific options should go under the `[mysqld]` section. Put options specific to the embedded MySQL server library in the `[embedded]` section. Options specific to applications go under section labeled `[ApplicationName_SERVER]`. See [Section 4.2.2.2](#), “Using Option Files”.

## 28.1.4. Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

### Example 1

`test1_libmysqld.c`

```
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;

static char *server_options[] = \
 { "mysql_test", "--defaults-file=my.cnf", NULL };
int num_elements = (sizeof(server_options) / sizeof(char *)) - 1;

static char *server_groups[] = { "libmysqld_server",
 "libmysqld_client", NULL };

int main(void)
{
 mysql_library_init(num_elements, server_options, server_groups);
 mysql = mysql_init(NULL);
 mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
 mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);
```

```

mysql_real_connect(mysql, NULL,NULL,NULL, "database1", 0,NULL,0);

mysql_query(mysql, "SELECT column1, column2 FROM table1");

results = mysql_store_result(mysql);

while((record = mysql_fetch_row(results))) {
 printf("%s - %s \n", record[0], record[1]);
}

mysql_free_result(results);
mysql_close(mysql);
mysql_library_end();

return 0;
}

```

Here is the command line for compiling the above program:

```

gcc test1_libmysqld.c -o test1_libmysqld -lz \
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`

```

## Example 2

To try out the example, create an `test2_libmysqld` directory at the same level as the MySQL source directory. Save the `test2_libmysqld.c` source and the `GNUmakefile` in the directory, and run GNU `make` from inside the `test2_libmysqld` directory.

### test2\_libmysqld.c

```

/*
 * A simple example client, using the embedded MySQL server library
 */

#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
 "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int
main(int argc, char **argv)
{
 MYSQL *one, *two;

 /* mysql_library_init() must be called before any other mysql
 * functions.
 *
 * You can use mysql_library_init(0, NULL, NULL), and it
 * initializes the server using groups = {
 * "server", "embedded", NULL
 * }.
 *
 * In your $HOME/.my.cnf file, you probably want to put:
 */

 [test2_libmysqld_SERVER]
 language = /path/to/source/of/mysql/sql/share/english

 * You could, of course, modify argc and argv before passing
 * them to this function. Or you could create new ones in any
 * way you like. But all of the arguments in argv (except for
 * argv[0], which is the program name) should be valid options
 * for the MySQL server.
 *
 * If you link this client against the normal mysqlclient
 * library, this function is just a stub that does nothing.
 */
 mysql_library_init(argc, argv, (char **)server_groups);

 one = db_connect("test");
 two = db_connect(NULL);

 db_do_query(one, "SHOW TABLE STATUS");
 db_do_query(two, "SHOW DATABASES");

 mysql_close(two);
 mysql_close(one);

 /* This must be called after all other mysql functions */
 mysql_library_end();

 exit(EXIT_SUCCESS);
}

```

```

static void
die(MYSQL *db, char *fmt, ...)
{
 va_list ap;
 va_start(ap, fmt);
 vfprintf(stderr, fmt, ap);
 va_end(ap);
 (void)putc('\n', stderr);
 if (db)
 db_disconnect(db);
 exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
 MYSQL *db = mysql_init(NULL);
 if (!db)
 die(db, "mysql_init failed: no memory");
 /*
 * Notice that the client and server use separate group names.
 * This is critical, because the server does not accept the
 * client's options, and vice versa.
 */
 mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
 if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
 die(db, "mysql_real_connect failed: %s", mysql_error(db));

 return db;
}

void
db_disconnect(MYSQL *db)
{
 mysql_close(db);
}

void
db_do_query(MYSQL *db, const char *query)
{
 if (mysql_query(db, query) != 0)
 goto err;

 if (mysql_field_count(db) > 0)
 {
 MYSQL_RES *res;
 MYSQL_ROW row, end_row;
 int num_fields;

 if (!(res = mysql_store_result(db)))
 goto err;
 num_fields = mysql_num_fields(res);
 while ((row = mysql_fetch_row(res)))
 {
 (void)fputs(">> ", stdout);
 for (end_row = row + num_fields; row < end_row; ++row)
 (void)printf("%s\t", row ? (char*)*row : "NULL");
 (void)fputc('\n', stdout);
 }
 (void)fputc('\n', stdout);
 mysql_free_result(res);
 }
 else
 (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));

 return;
err:
 die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);
}

```

### GNUmakefile

```

This assumes the MySQL software is installed in /usr/local/mysql
inc := /usr/local/mysql/include/mysql
lib := /usr/local/mysql/lib

If you have not installed the MySQL software yet, try this instead
#inc := $(HOME)/mysql-5.1/include
#lib := $(HOME)/mysql-5.1/libmysqld

CC := gcc
CPPFLAGS := -I$(inc) -D_THREAD_SAFE -D_REENTRANT
CFLAGS := -g -W -Wall
LDFLAGS := -static
You can change -lmysqld to -mysqlclient to use the
client/server library
LDLIBS = -L$(lib) -lmysqld -lz -lm -ldl -lcrypt

ifneq (,$(shell grep FreeBSD /COPYRIGHT 2>/dev/null))
FreeBSD
LDFLAGS += -pthread
else
Assume Linux
LDLIBS += -lpthread

```

```

endif
This works for simple one-file test programs
sources := $(wildcard *.c)
objects := $(patsubst %c,%o,$(sources))
targets := $(basename $(sources))

all: $(targets)

clean:
 rm -f $(targets) $(objects) *.core

```

### 28.1.5. Licensing the Embedded Server

We encourage everyone to promote free software by releasing code under the GPL or a compatible license. For those who are not able to do this, another option is to purchase a commercial license for the MySQL code from MySQL AB. For details, please see <http://www.mysql.com/company/legal/licensing/>.

## 28.2. MySQL C API

The C API code is distributed with MySQL. It is included in the `mysqlclient` library and allows C programs to access a database.

Many of the clients in the MySQL source distribution are written in C. If you are looking for examples that demonstrate how to use the C API, take a look at these clients. You can find these in the `clients` directory in the MySQL source distribution.

Most of the other client APIs (all except Connector/J and Connector/NET) use the `mysqlclient` library to communicate with the MySQL server. This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs, because they are referenced from the library. See [Chapter 4, MySQL Programs](#), for a list of these variables.

The client has a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (the maximum is 16MB). Because buffer sizes are increased only as demand warrants, simply increasing the default maximum limit does not in itself cause more resources to be used. This size check is mostly a check for erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each thread's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have `BLOB` values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The client's default maximum is 16MB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter when the server is started. See [Section 7.5.2, "Tuning Server Parameters"](#).

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

For programming with threads, see [Section 28.2.16, "How to Make a Threaded Client"](#). For creating a standalone application which includes the "server" and "client" in the same program (and does not communicate with an external MySQL server), see [Section 28.1, "libmysqld, the Embedded MySQL Server Library"](#).

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about using the C API in the Knowledge Base articles, [The C API](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

### 28.2.1. C API Data Types

This section describes C API data types other than those used for prepared statements. For information about the latter, see [Section 28.2.5, "C API Prepared Statement Data types"](#).

- `MYSQL`

This structure represents a handle to one database connection. It is used for almost all MySQL functions. You should not try to make a copy of a `MYSQL` structure. There is no guarantee that such a copy will be usable.

- `MYSQL_RES`

This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- `MYSQL_ROW`

This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- `MYSQL_FIELD`

This structure contains information about a field, such as the field's name, type, and size. Its members are described in more detail here. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- `MYSQL_FIELD_OFFSET`

This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- `my_ulonglong`

The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of 0 to 1.84e19.

On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

```
printf ("Number of rows: %lu\n",
 (unsigned long) mysql_num_rows(result));
```

- `my_bool`

A boolean type, for values that are true (non-zero) or false (zero).

The `MYSQL_FIELD` structure contains the members listed here:

- `char * name`

The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias.

- `char * org_name`

The name of the field, as a null-terminated string. Aliases are ignored.

- `char * table`

The name of the table containing this field, if it isn't a calculated field. For calculated fields, the `table` value is an empty string. If the column is selected from a view, `table` names the view. If the table or view was given an alias with an `AS` clause, the value of `table` is the alias. For a `UNION`, the value is the empty string.

- `char * org_table`

The name of the table, as a null-terminated string. Aliases are ignored. If the column is selected from a view, `org_table` names the underlying table. For a `UNION`, the value is the empty string.

- `char * db`

The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string. For a `UNION`, the value is the empty string.

- `char * catalog`

The catalog name. This value is always `"def"`.

- `char * def`

The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `unsigned long length`

The width of the field. This corresponds to the display length, in bytes.

- `unsigned long max_length`

The maximum width of the field for the result set (the length in bytes of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

The value of `max_length` is the length of the string representation of the values in the result set. For example, if you retrieve a `FLOAT` column and the “widest” value is `-12.345`, `max_length` is 7 (the length of `'-12.345'`).

If you are using prepared statements, `max_length` is not set by default because for the binary protocol the lengths of the values depend on the types of the values in the result set. (See [Section 28.2.5, “C API Prepared Statement Data types”](#).) If you want the `max_length` values anyway, enable the `STMT_ATTR_UPDATE_MAX_LENGTH` option with `mysql_stmt_attr_set()` and the lengths will be set when you call `mysql_stmt_store_result()`. (See [Section 28.2.7.3, “mysql\\_stmt\\_attr\\_set\(\)”](#), and [Section 28.2.7.27, “mysql\\_stmt\\_store\\_result\(\)”](#).)

- `unsigned int name_length`

The length of `name`.

- `unsigned int org_name_length`

The length of `org_name`.

- `unsigned int table_length`

The length of `table`.

- `unsigned int org_table_length`

The length of `org_table`.

- `unsigned int db_length`

The length of `db`.

- `unsigned int catalog_length`

The length of `catalog`.

- `unsigned int def_length`

The length of `def`.

- `unsigned int flags`

Different bit-flags for the field. The `flags` value may have zero or more of the following bits set:

| Flag Value                         | Flag Description                                                 |
|------------------------------------|------------------------------------------------------------------|
| <code>NOT_NULL_FLAG</code>         | Field can't be <code>NULL</code>                                 |
| <code>PRI_KEY_FLAG</code>          | Field is part of a primary key                                   |
| <code>UNIQUE_KEY_FLAG</code>       | Field is part of a unique key                                    |
| <code>MULTIPLE_KEY_FLAG</code>     | Field is part of a non-unique key                                |
| <code>UNSIGNED_FLAG</code>         | Field has the <code>UNSIGNED</code> attribute                    |
| <code>ZEROFILL_FLAG</code>         | Field has the <code>ZEROFILL</code> attribute                    |
| <code>BINARY_FLAG</code>           | Field has the <code>BINARY</code> attribute                      |
| <code>AUTO_INCREMENT_FLAG</code>   | Field has the <code>AUTO_INCREMENT</code> attribute              |
| <code>ENUM_FLAG</code>             | Field is an <code>ENUM</code> (deprecated)                       |
| <code>SET_FLAG</code>              | Field is a <code>SET</code> (deprecated)                         |
| <code>BLOB_FLAG</code>             | Field is a <code>BLOB</code> or <code>TEXT</code> (deprecated)   |
| <code>TIMESTAMP_FLAG</code>        | Field is a <code>TIMESTAMP</code> (deprecated)                   |
| <code>NO_DEFAULT_VALUE_FLAG</code> | Field has no default value; see additional notes following table |

Use of the `BLOB_FLAG`, `ENUM_FLAG`, `SET_FLAG`, and `TIMESTAMP_FLAG` flags is deprecated because they indicate the type of a field rather than an attribute of its type. It is preferable to test `field->type` against `MYSQL_TYPE_BLOB`,

`MYSQL_TYPE_ENUM`, `MYSQL_TYPE_SET`, or `MYSQL_TYPE_TIMESTAMP` instead.

`NUM_FLAG` indicates that a column is numeric. This includes columns with a type of `MYSQL_TYPE_DECIMAL`, `MYSQL_TYPE_TINY`, `MYSQL_TYPE_SHORT`, `MYSQL_TYPE_LONG`, `MYSQL_TYPE_FLOAT`, `MYSQL_TYPE_DOUBLE`, `MYSQL_TYPE_NULL`, `MYSQL_TYPE_TIMESTAMP`, `MYSQL_TYPE_LONGLONG`, `MYSQL_TYPE_INT24`, and `MYSQL_TYPE_YEAR`.

`NO_DEFAULT_VALUE_FLAG` indicates that a column has no `DEFAULT` clause in its definition. This does not apply to `NULL` columns (because such columns have a default of `NULL`), or to `AUTO_INCREMENT` columns (which have an implied default value).

The following example illustrates a typical use of the `flags` value:

```
if (field->flags & NOT_NULL_FLAG)
 printf("Field can't be null\n");
```

You may use the following convenience macros to determine the boolean status of the `flags` value:

| Flag Status                     | Description                                                                                                           |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>IS_NOT_NULL(flags)</code> | True if this field is defined as <code>NOT NULL</code>                                                                |
| <code>IS_PRI_KEY(flags)</code>  | True if this field is a primary key                                                                                   |
| <code>IS_BLOB(flags)</code>     | True if this field is a <code>BLOB</code> or <code>TEXT</code> (deprecated; test <code>field-&gt;type</code> instead) |

- `unsigned int decimals`

The number of decimals for numeric fields.

- `unsigned int charsetnr`

An ID number that indicates the character set/collation pair for the field.

To distinguish between binary and non-binary data for string data types, check whether the `charsetnr` value is 63. If so, the character set is `binary`, which indicates binary rather than non-binary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

`charsetnr` values are the same as those displayed in the `Id` column of the `SHOW COLLATION` statement or the `ID` column of the `INFORMATION_SCHEMA.COLLATIONS` table. You can use those information sources to see which character set and collation specific `charsetnr` values indicate:

```
mysql> SHOW COLLATION WHERE Id = 63;
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| binary | binary | 63 | Yes | Yes | 1 |
+-----+-----+-----+-----+-----+-----+

mysql> SELECT COLLATION_NAME, CHARACTER_SET_NAME
-> FROM INFORMATION_SCHEMA.COLLATIONS WHERE ID = 33;
+-----+-----+
| COLLATION_NAME | CHARACTER_SET_NAME |
+-----+-----+
| utf8_general_ci | utf8 |
+-----+-----+
```

- `enum enum_field_types type`

The type of the field. The `type` value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

| Type Value                         | Type Description                                            |
|------------------------------------|-------------------------------------------------------------|
| <code>MYSQL_TYPE_TINY</code>       | <code>TINYINT</code> field                                  |
| <code>MYSQL_TYPE_SHORT</code>      | <code>SMALLINT</code> field                                 |
| <code>MYSQL_TYPE_LONG</code>       | <code>INTEGER</code> field                                  |
| <code>MYSQL_TYPE_INT24</code>      | <code>MEDIUMINT</code> field                                |
| <code>MYSQL_TYPE_LONGLONG</code>   | <code>BIGINT</code> field                                   |
| <code>MYSQL_TYPE_DECIMAL</code>    | <code>DECIMAL</code> or <code>NUMERIC</code> field          |
| <code>MYSQL_TYPE_NEWDECIMAL</code> | Precision math <code>DECIMAL</code> or <code>NUMERIC</code> |

|                                    |                                                                                                            |
|------------------------------------|------------------------------------------------------------------------------------------------------------|
| <code>MYSQL_TYPE_FLOAT</code>      | <code>FLOAT</code> field                                                                                   |
| <code>MYSQL_TYPE_DOUBLE</code>     | <code>DOUBLE</code> or <code>REAL</code> field                                                             |
| <code>MYSQL_TYPE_BIT</code>        | <code>BIT</code> field                                                                                     |
| <code>MYSQL_TYPE_TIMESTAMP</code>  | <code>TIMESTAMP</code> field                                                                               |
| <code>MYSQL_TYPE_DATE</code>       | <code>DATE</code> field                                                                                    |
| <code>MYSQL_TYPE_TIME</code>       | <code>TIME</code> field                                                                                    |
| <code>MYSQL_TYPE_DATETIME</code>   | <code>DATETIME</code> field                                                                                |
| <code>MYSQL_TYPE_YEAR</code>       | <code>YEAR</code> field                                                                                    |
| <code>MYSQL_TYPE_STRING</code>     | <code>CHAR</code> or <code>BINARY</code> field                                                             |
| <code>MYSQL_TYPE_VAR_STRING</code> | <code>VARCHAR</code> or <code>VARBINARY</code> field                                                       |
| <code>MYSQL_TYPE_BLOB</code>       | <code>BLOB</code> or <code>TEXT</code> field (use <code>max_length</code> to determine the maximum length) |
| <code>MYSQL_TYPE_SET</code>        | <code>SET</code> field                                                                                     |
| <code>MYSQL_TYPE_ENUM</code>       | <code>ENUM</code> field                                                                                    |
| <code>MYSQL_TYPE_GEOMETRY</code>   | Spatial field                                                                                              |
| <code>MYSQL_TYPE_NULL</code>       | <code>NULL</code> -type field                                                                              |

You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM()` and it evaluates to `TRUE` if the field is numeric:

```
if (IS_NUM(field->type))
 printf("Field is numeric\n");
```

## 28.2.2. C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See [Section 28.2.3, “C API Function Descriptions”](#).

| Function                                | Description                                                                                                                                                               |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>my_init()</code>                  | Initialize global variables, and thread handler in thread-safe programs                                                                                                   |
| <code>mysql_affected_rows()</code>      | Returns the number of rows changed/deleted/inserted by the last <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> query                                  |
| <code>mysql_autocommit()</code>         | Toggles autocommit mode on/off                                                                                                                                            |
| <code>mysql_change_user()</code>        | Changes user and database on an open connection                                                                                                                           |
| <code>mysql_character_set_name()</code> | Return default character set name for current connection                                                                                                                  |
| <code>mysql_close()</code>              | Closes a server connection                                                                                                                                                |
| <code>mysql_commit()</code>             | Commits the transaction                                                                                                                                                   |
| <code>mysql_connect()</code>            | Connects to a MySQL server (this function is deprecated; use <code>mysql_real_connect()</code> instead)                                                                   |
| <code>mysql_create_db()</code>          | Creates a database (this function is deprecated; use the SQL statement <code>CREATE DATABASE</code> instead)                                                              |
| <code>mysql_data_seek()</code>          | Seeks to an arbitrary row number in a query result set                                                                                                                    |
| <code>mysql_debug()</code>              | Does a <code>DEBUG_PUSH</code> with the given string                                                                                                                      |
| <code>mysql_drop_db()</code>            | Drops a database (this function is deprecated; use the SQL statement <code>DROP DATABASE</code> instead)                                                                  |
| <code>mysql_dump_debug_info()</code>    | Makes the server write debug information to the log                                                                                                                       |
| <code>mysql_eof()</code>                | Determines whether the last row of a result set has been read (this function is deprecated; <code>mysql_errno()</code> or <code>mysql_error()</code> may be used instead) |
| <code>mysql_errno()</code>              | Returns the error number for the most recently invoked MySQL function                                                                                                     |
| <code>mysql_error()</code>              | Returns the error message for the most recently invoked MySQL function                                                                                                    |
| <code>mysql_escape_string()</code>      | Escapes special characters in a string for use in an SQL statement                                                                                                        |
| <code>mysql_fetch_field()</code>        | Returns the type of the next table field                                                                                                                                  |

|                                             |                                                                                                                                     |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>mysql_fetch_field_direct()</code>     | Returns the type of a table field, given a field number                                                                             |
| <code>mysql_fetch_fields()</code>           | Returns an array of all field structures                                                                                            |
| <code>mysql_fetch_lengths()</code>          | Returns the lengths of all columns in the current row                                                                               |
| <code>mysql_fetch_row()</code>              | Fetches the next row from the result set                                                                                            |
| <code>mysql_field_count()</code>            | Returns the number of result columns for the most recent statement                                                                  |
| <code>mysql_field_seek()</code>             | Puts the column cursor on a specified column                                                                                        |
| <code>mysql_field_tell()</code>             | Returns the position of the field cursor used for the last <code>mysql_fetch_field()</code>                                         |
| <code>mysql_free_result()</code>            | Frees memory used by a result set                                                                                                   |
| <code>mysql_get_character_set_info()</code> | Return information about default character set                                                                                      |
| <code>mysql_get_client_info()</code>        | Returns client version information as a string                                                                                      |
| <code>mysql_get_client_version()</code>     | Returns client version information as an integer                                                                                    |
| <code>mysql_get_host_info()</code>          | Returns a string describing the connection                                                                                          |
| <code>mysql_get_proto_info()</code>         | Returns the protocol version used by the connection                                                                                 |
| <code>mysql_get_server_info()</code>        | Returns the server version number                                                                                                   |
| <code>mysql_get_server_version()</code>     | Returns version number of server as an integer                                                                                      |
| <code>mysql_get_ssl_cipher()</code>         | Return current SSL cipher                                                                                                           |
| <code>mysql_hex_string()</code>             | Encode string in hexadecimal format                                                                                                 |
| <code>mysql_info()</code>                   | Returns information about the most recently executed query                                                                          |
| <code>mysql_init()</code>                   | Gets or initializes a <code>MYSQL</code> structure                                                                                  |
| <code>mysql_insert_id()</code>              | Returns the ID generated for an <code>AUTO_INCREMENT</code> column by the previous query                                            |
| <code>mysql_kill()</code>                   | Kills a given thread                                                                                                                |
| <code>mysql_library_end()</code>            | Finalize the MySQL C API library                                                                                                    |
| <code>mysql_library_init()</code>           | Initialize the MySQL C API library                                                                                                  |
| <code>mysql_list_dbs()</code>               | Returns database names matching a simple regular expression                                                                         |
| <code>mysql_list_fields()</code>            | Returns field names matching a simple regular expression                                                                            |
| <code>mysql_list_processes()</code>         | Returns a list of the current server threads                                                                                        |
| <code>mysql_list_tables()</code>            | Returns table names matching a simple regular expression                                                                            |
| <code>mysql_more_results()</code>           | Checks whether any more results exist                                                                                               |
| <code>mysql_next_result()</code>            | Returns/initiates the next result in multiple-statement executions                                                                  |
| <code>mysql_num_fields()</code>             | Returns the number of columns in a result set                                                                                       |
| <code>mysql_num_rows()</code>               | Returns the number of rows in a result set                                                                                          |
| <code>mysql_options()</code>                | Sets connect options for <code>mysql_real_connect()</code>                                                                          |
| <code>mysql_ping()</code>                   | Checks whether the connection to the server is working, reconnecting as necessary                                                   |
| <code>mysql_query()</code>                  | Executes an SQL query specified as a null-terminated string                                                                         |
| <code>mysql_real_connect()</code>           | Connects to a MySQL server                                                                                                          |
| <code>mysql_real_escape_string()</code>     | Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection |
| <code>mysql_real_query()</code>             | Executes an SQL query specified as a counted string                                                                                 |
| <code>mysql_refresh()</code>                | Flush or reset tables and caches                                                                                                    |
| <code>mysql_reload()</code>                 | Tells the server to reload the grant tables                                                                                         |
| <code>mysql_rollback()</code>               | Rolls back the transaction                                                                                                          |
| <code>mysql_row_seek()</code>               | Seeks to a row offset in a result set, using value returned from <code>mysql_row_tell()</code>                                      |
| <code>mysql_row_tell()</code>               | Returns the row cursor position                                                                                                     |
| <code>mysql_select_db()</code>              | Selects a database                                                                                                                  |
| <code>mysql_server_end()</code>             | Finalize the MySQL C API library                                                                                                    |
| <code>mysql_server_init()</code>            | Initialize the MySQL C API library                                                                                                  |
| <code>mysql_set_character_set()</code>      | Set default character set for current connection                                                                                    |
| <code>mysql_set_local_infile_defa</code>    | Set the <code>LOAD DATA LOCAL INFILE</code> handler callbacks to their default values                                               |

|                                               |                                                                                    |
|-----------------------------------------------|------------------------------------------------------------------------------------|
| <code>ult()</code>                            |                                                                                    |
| <code>mysql_set_local_infile_handler()</code> | Install application-specific <code>LOAD DATA LOCAL INFILE</code> handler callbacks |
| <code>mysql_set_server_option()</code>        | Sets an option for the connection (like <code>multi-statements</code> )            |
| <code>mysql_sqlstate()</code>                 | Returns the <code>SQLSTATE</code> error code for the last error                    |
| <code>mysql_shutdown()</code>                 | Shuts down the database server                                                     |
| <code>mysql_ssl_set()</code>                  | Prepare to establish SSL connection to server                                      |
| <code>mysql_stat()</code>                     | Returns the server status as a string                                              |
| <code>mysql_store_result()</code>             | Retrieves a complete result set to the client                                      |
| <code>mysql_thread_end()</code>               | Finalize thread handler                                                            |
| <code>mysql_thread_id()</code>                | Returns the current thread ID                                                      |
| <code>mysql_thread_init()</code>              | Initialize thread handler                                                          |
| <code>mysql_thread_safe()</code>              | Returns 1 if the clients are compiled as thread-safe                               |
| <code>mysql_use_result()</code>               | Initiates a row-by-row result set retrieval                                        |
| <code>mysql_warning_count()</code>            | Returns the warning count for the previous SQL statement                           |

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. This function exists in both the `mysqlclient` C client library and the `mysqld` embedded server library, so it is used whether you build a regular client program by linking with the `-libmysqlclient` flag, or an embedded server application by linking with the `-libmysqld` flag.
2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.
3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)
4. Close the connection to the MySQL server by calling `mysql_close()`.
5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you don't call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

In a non-multi-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly via `mysql_init()`. This should be done prior to any other client library call.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the hostname, username, and password). Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of 1 in versions of the API older than 5.0.3, or 0 in newer versions. A value of 1 for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior. When you are done with the connection, call `mysql_close()` to terminate it.

While a connection is active, the client may send SQL statements to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-`SELECT` query (for example, `INSERT`, `UPDATE`, `DELETE`), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For `SELECT` queries, you retrieve the selected rows as a result set. (Note that some statements are `SELECT`-like in that they return rows. These include `SHOW`, `DESCRIBE`, and `EXPLAIN`. They should be treated the same way as `SELECT` statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Client programs should choose the approach that is most appropriate for their requirements. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you don't have random access to rows within the result set (you can only access rows sequentially), and you don't know how many rows are in the result set until you have retrieved them all. Furthermore, you **must** retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a `SELECT`. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the statement was a `SELECT` and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the statement returned no data (indicating that it was an `INSERT`, `UPDATE`, `DELETE`, and so forth), and was not expected to return rows. If `mysql_field_count()` is non-zero, the statement should have returned rows, but didn't. This indicates that the statement was a `SELECT` that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` allow you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, allowing you to determine when an error occurred and what it was.

### 28.2.3. C API Function Descriptions

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-`NULL` value to indicate success or a `NULL` value to indicate an error, and functions returning an integer return zero to indicate success or non-zero to indicate an error. Note that “non-zero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```
if (result) /* correct */
 ... error ...

if (result < 0) /* incorrect */
 ... error ...

if (result == -1) /* incorrect */
 ... error ...
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

MySQL Enterprise subscribers will find more information about the C API functions in the Knowledge Base articles, [The C API](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

### 28.2.3.1. `mysql_affected_rows()`

```
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

#### Description

After executing a statement with `mysql_query()` or `mysql_real_query()`, returns the number of rows changed (for `UPDATE`), deleted (for `DELETE`), or inserted (for `INSERT`). For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

#### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`. Because `mysql_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

#### Errors

None.

#### Example

```
char *stmt = "UPDATE products SET cost=cost*1.25 WHERE group=10";
mysql_query(&mysql, stmt);
printf("%ld products updated",
 (long) mysql_affected_rows(&mysql));
```

For `UPDATE` statements, if you specify the `CLIENT_FOUND_ROWS` flag when connecting to `mysqld`, `mysql_affected_rows()` returns the number of rows matched by the `WHERE` clause. Otherwise, the default behavior is to return the number of rows actually changed.

Note that when you use a `REPLACE` command, `mysql_affected_rows()` returns 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

If you use `INSERT ... ON DUPLICATE KEY UPDATE` to insert a row, `mysql_affected_rows()` returns 1 if the row is inserted as a new row and 2 if an existing row is updated.

`mysql_affected_rows()` returns 0 following a `CALL` statement for a stored procedure that contains a statement that modifies rows because in this case `mysql_insert_id()` applies to `CALL` and not the statement within the procedure. Within the procedure, you can use `ROW_COUNT()` at the SQL level to obtain the `AUTO_INCREMENT` value.

### 28.2.3.2. `mysql_autocommit()`

```
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

#### Description

Sets autocommit mode on if `mode` is 1, off if `mode` is 0.

#### Return Values

Zero if successful. Non-zero if an error occurred.

#### Errors

None.

### 28.2.3.3. `mysql_change_user()`

```
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char *password, const char *db)
```

#### Description

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by

`mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_change_user()` fails if the connected user cannot be authenticated or doesn't have permission to use the database. In this case, the user and database are not changed.

The `db` parameter may be set to `NULL` if you don't want to have a default database.

This command resets the state as if one had done a new connect. (See [Section 28.2.13](#), “Controlling Automatic Reconnect Behavior”.) It always performs a `ROLLBACK` of any active transactions, closes and drops all temporary tables, and unlocks all locked tables. Session system variables are reset to the values of the corresponding global system variables. Prepared statements are released and `HANDLER` variables are closed. Locks acquired with `GET_LOCK()` are released. These effects occur even if the user didn't change.

### Return Values

Zero for success. Non-zero if an error occurred.

### Errors

The same that you can get from `mysql_real_connect()`.

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.
- `ER_UNKNOWN_COM_ERROR`  
The MySQL server doesn't implement this command (probably an old server).
- `ER_ACCESS_DENIED_ERROR`  
The user or password was wrong.
- `ER_BAD_DB_ERROR`  
The database didn't exist.
- `ER_DBACCESS_DENIED_ERROR`  
The user did not have access rights to the database.
- `ER_WRONG_DB_NAME`  
The database name was too long.

### Example

```
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
 fprintf(stderr, "Failed to change user. Error: %s\n",
 mysql_error(&mysql));
}
```

## 28.2.3.4. `mysql_character_set_name()`

```
const char *mysql_character_set_name(MYSQL *mysql)
```

### Description

Returns the default character set name for the current connection.

**Return Values**

The default character set name

**Errors**

None.

### 28.2.3.5. `mysql_close()`

```
void mysql_close(MYSQL *mysql)
```

**Description**

Closes a previously opened connection. `mysql_close()` also deallocates the connection handle pointed to by `mysql` if the handle was allocated automatically by `mysql_init()` or `mysql_connect()`.

**Return Values**

None.

**Errors**

None.

### 28.2.3.6. `mysql_commit()`

```
my_bool mysql_commit(MYSQL *mysql)
```

**Description**

Commits the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

**Return Values**

Zero if successful. Non-zero if an error occurred.

**Errors**

None.

### 28.2.3.7. `mysql_connect()`

```
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd)
```

**Description**

This function is deprecated. Use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case, the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you can't retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

**Return Values**

Same as for `mysql_real_connect()`.

**Errors**

Same as for `mysql_real_connect()`.

### 28.2.3.8. `mysql_create_db()`

```
int mysql_create_db(MYSQL *mysql, const char *db)
```

#### Description

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

#### Return Values

Zero if the database was created successfully. Non-zero if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

#### Example

```
if(mysql_create_db(&mysql, "my_database"))
{
 fprintf(stderr, "Failed to create new database. Error: %s\n",
 mysql_error(&mysql));
}
```

### 28.2.3.9. `mysql_data_seek()`

```
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

#### Description

Seeks to an arbitrary row in a query result set. The `offset` value is a row number and should be in the range from 0 to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

#### Return Values

None.

#### Errors

None.

### 28.2.3.10. `mysql_debug()`

```
void mysql_debug(const char *debug)
```

#### Description

Does a `DEBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See [MySQL Internals: Porting](#).

**Return Values**

None.

**Errors**

None.

**Example**

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```
mysql_debug("d:t:O,/tmp/client.trace");
```

### 28.2.3.11. `mysql_drop_db()`

```
int mysql_drop_db(MYSQL *mysql, const char *db)
```

**Description**

Drops the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

**Return Values**

Zero if the database was dropped successfully. Non-zero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

**Example**

```
if(mysql_drop_db(&mysql, "my_database"))
 fprintf(stderr, "Failed to drop the database: Error: %s\n",
 mysql_error(&mysql));
```

### 28.2.3.12. `mysql_dump_debug_info()`

```
int mysql_dump_debug_info(MYSQL *mysql)
```

**Description**

Instructs the server to write some debug information to the log. For this to work, the connected user must have the `SUPER` privilege.

**Return Values**

Zero if the command was successful. Non-zero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 28.2.3.13. `mysql_eof()`

```
mysql_bool mysql_eof(MYSQL_RES *result)
```

#### Description

This function is deprecated. `mysql_errno()` or `mysql_error()` may be used instead.

`mysql_eof()` determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to `mysql_store_result()`, the client receives the entire set in one operation. In this case, a `NULL` return from `mysql_fetch_row()` always means the end of the result set has been reached and it is unnecessary to call `mysql_eof()`. When used with `mysql_store_result()`, `mysql_eof()` always returns true.

On the other hand, if you use `mysql_use_result()` to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call `mysql_fetch_row()` repeatedly. Because an error may occur on the connection during this process, a `NULL` return value from `mysql_fetch_row()` does not necessarily mean the end of the result set was reached normally. In this case, you can use `mysql_eof()` to determine what happened. `mysql_eof()` returns a non-zero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

#### Return Values

Zero if no error occurred. Non-zero if the end of the result set has been reached.

#### Errors

None.

#### Example

The following example shows how you might use `mysql_eof()`:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
 // do something with data
}
if(!mysql_eof(result)) // mysql_fetch_row() failed due to an error
{
 fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
 // do something with data
}
if(mysql_errno(&mysql)) // mysql_fetch_row() failed due to an error
{
 fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

### 28.2.3.14. `mysql_errno()`

```
unsigned int mysql_errno(MYSQL *mysql)
```

#### Description

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix B, Errors, Error Codes, and Common Problems](#).

Note that some functions like `mysql_fetch_row()` don't set `mysql_errno()` if they succeed.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

MySQL-specific error numbers returned by `mysql_errno()` differ from SQLSTATE values returned by `mysql_sqlstate()`. For example, the `mysql` client program displays errors using the following format, where `1146` is the `mysql_errno()` value and `'42S02'` is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

#### Return Values

An error code value for the last `mysql_xxx()` call, if it failed. zero means no error occurred.

#### Errors

None.

### 28.2.3.15. `mysql_error()`

```
const char *mysql_error(MYSQL *mysql)
```

#### Description

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function didn't fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_error()`, the following two tests are equivalent:

```
if(*mysql_error(&mysql))
{
 // an error occurred
}

if(mysql_error(&mysql)[0])
{
 // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages. See [Section 9.3, "Setting the Error Message Language"](#).

#### Return Values

A null-terminated character string that describes the error. An empty string if no error occurred.

#### Errors

None.

### 28.2.3.16. `mysql_escape_string()`

You should use `mysql_real_escape_string()` instead!

This function is identical to `mysql_real_escape_string()` except that `mysql_escape_string()` takes a con-

nection handler as its first argument and escapes the string according to the current character set. `mysql_escape_string()` does not take a connection argument and does not respect the current character set.

### 28.2.3.17. `mysql_fetch_field()`

```
MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)
```

#### Description

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to `mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a `BLOB` field. (The 8KB size is chosen because MySQL doesn't know the maximum length for the `BLOB`. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

#### Return Values

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

#### Errors

None.

#### Example

```
MYSQL_FIELD *field;
while((field = mysql_fetch_field(result)))
{
 printf("field name %s\n", field->name);
}
```

### 28.2.3.18. `mysql_fetch_field_direct()`

```
MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned int fieldnr)
```

#### Description

Given a field number `fieldnr` for a column within a result set, returns that column's field definition as a `MYSQL_FIELD` structure. You may use this function to retrieve the definition for an arbitrary column. The value of `fieldnr` should be in the range from 0 to `mysql_num_fields(result)-1`.

#### Return Values

The `MYSQL_FIELD` structure for the specified column.

#### Errors

None.

#### Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *field;

num_fields = mysql_num_fields(result);
for(i = 0; i < num_fields; i++)
{
 field = mysql_fetch_field_direct(result, i);
 printf("Field %u is %s\n", i, field->name);
}
```

### 28.2.3.19. `mysql_fetch_fields()`

```
MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)
```

#### Description

Returns an array of all `MYSQL_FIELD` structures for a result set. Each structure provides the field definition for one column of the result set.

#### Return Values

An array of `MYSQL_FIELD` structures for all columns of a result set.

#### Errors

None.

#### Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;

num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
for(i = 0; i < num_fields; i++)
{
 printf("Field %u is %s\n", i, fields[i].name);
}
```

### 28.2.3.20. `mysql_fetch_lengths()`

```
unsigned long *mysql_fetch_lengths(MYSQL_RES *result)
```

#### Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling `strlen()`. In addition, if the result set contains binary data, you **must** use this function to determine the size of the data, because `strlen()` returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing `NULL` values is zero. To see how to distinguish these two cases, see the description for `mysql_fetch_row()`.

#### Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null characters). `NULL` if an error occurred.

#### Errors

`mysql_fetch_lengths()` is valid only for the current row of the result set. It returns `NULL` if you call it before calling `mysql_fetch_row()` or after retrieving all rows in the result.

#### Example

```
MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
 num_fields = mysql_num_fields(result);
 lengths = mysql_fetch_lengths(result);
 for(i = 0; i < num_fields; i++)
 {
 printf("Column %u is %lu bytes in length.\n",
 i, lengths[i]);
 }
}
```

### 28.2.3.21. `mysql_fetch_row()`

```
MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)
```

#### Description

Retrieves the next row of a result set. When used after `mysql_store_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve. When used after `mysql_use_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by `mysql_num_fields(result)`. If `row` holds the return value from a call to `mysql_fetch_row()`, pointers to the values are accessed as `row[0]` to `row[mysql_num_fields(result)-1]`. `NULL` values in the row are indicated by `NULL` pointers.

The lengths of the field values in the row may be obtained by calling `mysql_fetch_lengths()`. Empty fields and fields containing `NULL` both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is `NULL`, the field is `NULL`; otherwise, the field is empty.

### Return Values

A `MYSQL_ROW` structure for the next row. `NULL` if there are no more rows to retrieve or if an error occurred.

### Errors

Note that error is not reset between calls to `mysql_fetch_row()`

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### Example

```
MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;

num_fields = mysql_num_fields(result);
while ((row = mysql_fetch_row(result)))
{
 unsigned long *lengths;
 lengths = mysql_fetch_lengths(result);
 for(i = 0; i < num_fields; i++)
 {
 printf("[%s] ", (int) lengths[i],
 row[i] ? row[i] : "NULL");
 }
 printf("\n");
}
```

## 28.2.3.22. `mysql_field_count()`

```
unsigned int mysql_field_count(MYSQL *mysql)
```

### Description

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See [Section 28.2.14.1, “Why `mysql\_store\_result\(\)` Sometimes Returns `NULL` After `mysql\_query\(\)` Returns Success”](#).

### Return Values

An unsigned integer representing the number of columns in a result set.

### Errors

None.

### Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
 // error
}
```

```

}
else // query succeeded, process any data returned by it
{
 result = mysql_store_result(&mysql);
 if (result) // there are rows
 {
 num_fields = mysql_num_fields(result);
 // retrieve rows, then call mysql_free_result(result)
 }
 else // mysql_store_result() returned nothing; should it have?
 {
 if(mysql_field_count(&mysql) == 0)
 {
 // query does not return data
 // (it was not a SELECT)
 num_rows = mysql_affected_rows(&mysql);
 }
 else // mysql_store_result() should have returned data
 {
 fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
 }
 }
}
}

```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a `SELECT`.

### 28.2.3.23. `mysql_field_seek()`

```
MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result, MYSQL_FIELD_OFFSET offset)
```

#### Description

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an `offset` value of zero.

#### Return Values

The previous value of the field cursor.

#### Errors

None.

### 28.2.3.24. `mysql_field_tell()`

```
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

#### Description

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can be used as an argument to `mysql_field_seek()`.

#### Return Values

The current offset of the field cursor.

#### Errors

None.

### 28.2.3.25. `mysql_free_result()`

```
void mysql_free_result(MYSQL_RES *result)
```

#### Description

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, and so forth. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

#### Return Values

None.

**Errors**

None.

### 28.2.3.26. `mysql_get_character_set_info()`

```
void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO *cs)
```

**Description**

This function provides information about the default client character set. The default character set may be changed with the `mysql_set_character_set()` function.

**Example**

This example shows the fields that are available in the `MY_CHARSET_INFO` structure:

```
if (!mysql_set_character_set(&mysql, "utf8"))
{
 MY_CHARSET_INFO cs;
 mysql_get_character_set_info(&mysql, &cs);
 printf("character set information:\n");
 printf("character set+collation number: %d\n", cs.number);
 printf("character set name: %s\n", cs.name);
 printf("collation name: %s\n", cs.csname);
 printf("comment: %s\n", cs.comment);
 printf("directory: %s\n", cs.dir);
 printf("multi byte character min. length: %d\n", cs.mbminlen);
 printf("multi byte character max. length: %d\n", cs.mbmaxlen);
}
```

### 28.2.3.27. `mysql_get_client_info()`

```
const char *mysql_get_client_info(void)
```

**Description**

Returns a string that represents the client library version.

**Return Values**

A character string that represents the MySQL client library version.

**Errors**

None.

### 28.2.3.28. `mysql_get_client_version()`

```
unsigned long mysql_get_client_version(void)
```

**Description**

Returns an integer that represents the client library version. The value has the format `XYZZZ` where `X` is the major version, `YY` is the release level, and `ZZ` is the version number within the release level. For example, a value of `40102` represents a client library version of `4.1.2`.

**Return Values**

An integer that represents the MySQL client library version.

**Errors**

None.

### 28.2.3.29. `mysql_get_host_info()`

```
const char *mysql_get_host_info(MYSQL *mysql)
```

**Description**

Returns a string describing the type of connection in use, including the server hostname.

**Return Values**

A character string representing the server hostname and the connection type.

**Errors**

None.

**28.2.3.30. `mysql_get_proto_info()`**

```
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

**Description**

Returns the protocol version used by current connection.

**Return Values**

An unsigned integer representing the protocol version used by the current connection.

**Errors**

None.

**28.2.3.31. `mysql_get_server_info()`**

```
const char *mysql_get_server_info(MYSQL *mysql)
```

**Description**

Returns a string that represents the server version number.

**Return Values**

A character string that represents the server version number.

**Errors**

None.

**28.2.3.32. `mysql_get_server_version()`**

```
unsigned long mysql_get_server_version(MYSQL *mysql)
```

**Description**

Returns the version number of the server as an integer.

**Return Values**

A number that represents the MySQL server version in this format:

```
major_version*10000 + minor_version *100 + sub_version
```

For example, 5.1.5 is returned as 50105.

This function is useful in client programs for quickly determining whether some version-specific server capability exists.

**Errors**

None.

**28.2.3.33. `mysql_get_ssl_cipher()`**

```
const char *mysql_get_ssl_cipher(MYSQL *mysql)
```

**Description**

---

`mysql_get_ssl_cipher()` returns the SSL cipher used for the given connection to the server. `mysql` is the connection handler returned from `mysql_init()`.

This function was added in MySQL 5.1.11.

#### Return Values

A string naming the SSL cipher used for the connection, or `NULL` if no cipher is being used.

### 28.2.3.34. `mysql_hex_string()`

```
unsigned long mysql_hex_string(char *to, const char *from, unsigned long length)
```

#### Description

This function is used to create a legal SQL string that you can use in an SQL statement. See [Section 8.1.1, “Strings”](#).

The string in `from` is encoded to hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in `to` and a terminating null byte is appended.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. When `mysql_hex_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

The return value can be placed into an SQL statement using either `0xvalue` or `X'value'` format. However, the return value does not include the `0x` or `X' . . . '`. The caller must supply whichever of those is desired.

#### Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
end = strmov(end,"0x");
end += mysql_hex_string(end,"What's this",11);
end = strmov(end," ,0x");
end += mysql_hex_string(end,"binary data: \0\r\n",16);
*end++ = ')';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
 fprintf(stderr, "Failed to insert row, Error: %s\n",
 mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

#### Return Values

The length of the value placed into `to`, not including the terminating null character.

#### Errors

None.

### 28.2.3.35. `mysql_info()`

```
const char *mysql_info(MYSQL *mysql)
```

#### Description

Retrieves a string providing information about the most recently executed statement, but only for the statements listed here. For other statements, `mysql_info()` returns `NULL`. The format of the string varies depending on the type of statement, as described here. The numbers are illustrative only; the string contains values appropriate for the statement.

- `INSERT INTO ... SELECT ...`  
String format: `Records: 100 Duplicates: 0 Warnings: 0`
- `INSERT INTO ... VALUES (...),(...),(...)...`  
String format: `Records: 3 Duplicates: 0 Warnings: 0`

- `LOAD DATA INFILE ...`  
String format: `Records: 1 Deleted: 0 Skipped: 0 Warnings: 0`
- `ALTER TABLE`  
String format: `Records: 3 Duplicates: 0 Warnings: 0`
- `UPDATE`  
String format: `Rows matched: 40 Changed: 40 Warnings: 0`

Note that `mysql_info()` returns a non-NULL value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

#### Return Values

A character string representing additional information about the most recently executed statement. `NULL` if no information is available for the statement.

#### Errors

None.

### 28.2.3.36. `mysql_init()`

```
MYSQL *mysql_init(MYSQL *mysql)
```

#### Description

Allocates or initializes a `MYSQL` object suitable for `mysql_real_connect()`. If `mysql` is a `NULL` pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

#### Return Values

An initialized `MYSQL*` handle. `NULL` if there was insufficient memory to allocate a new object.

#### Errors

In case of insufficient memory, `NULL` is returned.

### 28.2.3.37. `mysql_insert_id()`

```
my_ulonglong mysql_insert_id(MYSQL *mysql)
```

#### Description

Returns the value generated for an `AUTO_INCREMENT` column by the previous `INSERT` or `UPDATE` statement. Use this function after you have performed an `INSERT` statement into a table that contains an `AUTO_INCREMENT` field, or have used `INSERT` or `UPDATE` to set a column value with `LAST_INSERT_ID(expr)`.

The return value of `mysql_insert_id()` is always zero unless explicitly updated under one of the following conditions:

- `INSERT` statements that store a value into an `AUTO_INCREMENT` column. This is true whether the value is automatically generated by storing the special values `NULL` or `0` into the column, or is an explicit non-special value.
- In the case of a multiple-row `INSERT` statement, the return value of `mysql_insert_id()` depends on the MySQL server version.

In MySQL 5.1.12 and later, `mysql_insert_id()` returns the *first* automatically generated `AUTO_INCREMENT` value that was *successfully* inserted. In MySQL 5.1.11 and earlier, `mysql_insert_id()` returns the *first* automatically generated `AUTO_INCREMENT` value, regardless of whether insertion of that value was successful.

If no rows are successfully inserted, `mysql_insert_id()` returns 0.

- Starting in MySQL 5.1.12, if an `INSERT ... SELECT` statement is executed, and no automatically generated value is successfully inserted, `mysql_insert_id()` returns the ID of the last inserted row.

- Starting in MySQL 5.1.12, if an `INSERT ... SELECT` statement uses `LAST_INSERT_ID(expr)`, `mysql_insert_id()` returns `expr`.
- `INSERT` statements that generate an `AUTO_INCREMENT` value by inserting `LAST_INSERT_ID(expr)` into any column or by updating any column to `LAST_INSERT_ID(expr)`.
- If the previous statement returned an error, the value of `mysql_insert_id()` is undefined.

For 5.1.12 and later, the return value of `mysql_insert_id()` can be simplified to the following sequence:

1. If there is an `AUTO_INCREMENT` column, and an automatically generated value was successfully inserted, return the first such value.
2. If `LAST_INSERT_ID(expr)` occurred in the statement, return `expr`, even if there was an `AUTO_INCREMENT` column in the affected table.
3. The return value varies depending on the statement used. When called after an `INSERT` statement:
  - If there is an `AUTO_INCREMENT` column in the table, and there were some explicit values for this column that were successfully inserted into the table, return the last of the explicit values.

When called after an `INSERT ... ON DUPLICATE KEY` statement:

- If there is an `AUTO_INCREMENT` column in the table and there were some explicit successfully inserted values, or some updated rows, return the last of the inserted or updated values.

`mysql_insert_id()` returns 0 if the previous statement does not use an `AUTO_INCREMENT` value. If you need to save the value for later, be sure to call `mysql_insert_id()` immediately after the statement that generates the value.

The value of `mysql_insert_id()` is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

The `LAST_INSERT_ID()` SQL function returns the value of the first automatically generated value that was successfully inserted (starting from 5.1.12) or the first automatically generated value if any rows were successfully inserted (before 5.1.12). `LAST_INSERT_ID()` is not reset between statements because the value of that function is maintained in the server. Another difference from `mysql_insert_id()` is that `LAST_INSERT_ID()` is not updated if you set an `AUTO_INCREMENT` column to a specific non-special value. See [Section 11.11.3, “Information Functions”](#).

`mysql_insert_id()` returns 0 following a `CALL` statement for a stored procedure that generates an `AUTO_INCREMENT` value because in this case `mysql_insert_id()` applies to `CALL` and not the statement within the procedure. Within the procedure, you can use `LAST_INSERT_ID()` at the SQL level to obtain the `AUTO_INCREMENT` value.

The reason for the differences between `LAST_INSERT_ID()` and `mysql_insert_id()` is that `LAST_INSERT_ID()` is made easy to use in scripts while `mysql_insert_id()` tries to provide more exact information about what happens to the `AUTO_INCREMENT` column.

### Return Values

Described in the preceding discussion.

### Errors

None.

## 28.2.3.38. `mysql_kill()`

```
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

### Description

Asks the server to kill the thread specified by `pid`.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `KILL` statement instead.

### Return Values

Zero for success. Non-zero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

**28.2.3.39. `mysql_library_end()`**

```
void mysql_library_end(void)
```

**Description**

This function finalizes the MySQL library. You should call it when you are done using the library (for example, after disconnecting from the server). The action taken by the call depends on whether your application is linked to the MySQL client library or the MySQL embedded server library. For a client program linked against the `libmysqlclient` library by using the `-lmysqlclient` flag, `mysql_library_end()` performs some memory management to clean up. For an embedded server application linked against the `libmysqld` library by using the `-lmysqld` flag, `mysql_library_end()` shuts down the embedded server and then cleans up.

See [Section 28.2.2, “C API Function Overview”](#), and [Section 28.2.3.40, “`mysql\_library\_init\(\)`”](#), for usage information.

**28.2.3.40. `mysql_library_init()`**

```
int mysql_library_init(int argc, char **argv, char **groups)
```

**Description**

This function should be called to initialize the MySQL library before you call any other MySQL function. If your application uses the embedded server, this call starts the server and initializes any subsystems (`mysys`, `InnoDB`, and so forth) that the server uses.

In a non-multi-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly via `mysql_init()`. This should be done prior to any other client library call.

After your application is done using the MySQL library, call `mysql_library_end()` to clean up. See [Section 28.2.3.39, “`mysql\_library\_end\(\)`”](#).

The `argc` and `argv` arguments are analogous to the arguments to `main()`. The first element of `argv` is ignored (it typically contains the program name). For convenience, `argc` may be 0 (zero) if there are no command-line arguments for the server. `mysql_library_init()` makes a copy of the arguments so it is safe to destroy `argv` or `groups` after the call.

If you want to connect to an external server without starting the embedded server, you have to specify a negative value for `argc`.

The `groups` argument should be an array of strings that indicate the groups in option files from which options should be read. See [Section 4.2.2.2, “Using Option Files”](#). The final entry in the array should be `NULL`. For convenience, if the `groups` argument itself is `NULL`, the `[server]` and `[embedded]` groups are used by default.

See [Section 28.2.2, “C API Function Overview”](#), for additional usage information.

**Example**

```
#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
 "this_program", /* this string is not used */
 "--datadir=.",
}
```

```

"--key_buffer_size=32M"
};
static char *server_groups[] = {
 "embedded",
 "server",
 "this_program_SERVER",
 (char *)NULL
};

int main(void) {
 if (mysql_library_init(sizeof(server_args) / sizeof(char *),
 server_args, server_groups)) {
 fprintf(stderr, "could not initialize MySQL library\n");
 exit(1);
 }

 /* Use any MySQL API functions here */

 mysql_library_end();

 return EXIT_SUCCESS;
}

```

**Return Values**

Zero if successful. Non-zero if an error occurred.

**28.2.3.41. `mysql_list_dbs()`**

```
MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)
```

**Description**

Returns a result set consisting of database names on the server that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “%” or “\_”, or may be a `NULL` pointer to match all databases. Calling `mysql_list_dbs()` is similar to executing the query `SHOW databases [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

**Return Values**

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

**28.2.3.42. `mysql_list_fields()`**

```
MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const char *wild)
```

**Description**

Returns a result set consisting of field names in the given table that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “%” or “\_”, or may be a `NULL` pointer to match all fields. Calling `mysql_list_fields()` is similar to executing the query `SHOW COLUMNS FROM tbl_name [LIKE wild]`.

Note that it's recommended that you use `SHOW COLUMNS FROM tbl_name` instead of `mysql_list_fields()`.

You must free the result set with `mysql_free_result()`.

#### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 28.2.3.43. `mysql_list_processes()`

```
MYSQL_RES *mysql_list_processes(MYSQL *mysql)
```

#### Description

Returns a result set describing the current server threads. This is the same kind of information as that reported by `mysqladmin processlist` or a `SHOW PROCESSLIST` query.

You must free the result set with `mysql_free_result()`.

#### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 28.2.3.44. `mysql_list_tables()`

```
MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)
```

#### Description

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “%” or “\_”, or may be a `NULL` pointer to match all tables. Calling `mysql_list_tables()` is similar to executing the query `SHOW tables [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

#### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 28.2.3.45. `mysql_more_results()`

```
my_bool mysql_more_results(MYSQL *mysql)
```

#### Description

This function is used when you execute multiple statements specified as a single statement string, or when you execute `CALL` statements, which can return multiple result sets.

`mysql_more_results()` true if more results exist from the currently executed statement, in which case the application must call `mysql_next_result()` to fetch the results.

#### Return Values

`TRUE` (1) if more results exist. `FALSE` (0) if no more results exist.

In most cases, you can call `mysql_next_result()` instead to test whether more results exist and initiate retrieval if so.

See [Section 28.2.9, “C API Handling of Multiple Statement Execution”](#), and [Section 28.2.3.46, “mysql\\_next\\_result\(\)”](#).

#### Errors

None.

### 28.2.3.46. `mysql_next_result()`

```
int mysql_next_result(MYSQL *mysql)
```

#### Description

This function is used when you execute multiple statements specified as a single statement string, or when you execute `CALL` statements, which can return multiple result sets.

If more statement results exist, `mysql_next_result()` reads the next statement result and returns the status back to the application.

Before calling `mysql_next_result()`, you must call `mysql_free_result()` for the preceding statement if it is a query that returned a result set.

After calling `mysql_next_result()` the state of the connection is as if you had called `mysql_real_query()` or `mysql_query()` for the next statement. This means that you can call `mysql_store_result()`, `mysql_warning_count()`, `mysql_affected_rows()`, and so forth.

If `mysql_next_result()` returns an error, no other statements are executed and there are no more results to fetch.

If your program executes stored procedures with the `CALL` SQL statement, you *must* set the `CLIENT_MULTI_RESULTS` flag explicitly, or implicitly by setting `CLIENT_MULTI_STATEMENTS` when you call `mysql_real_connect()`. This is because each `CALL` returns a result to indicate the call status, in addition to any results sets that might be returned by statements executed within the procedure. In addition, because `CALL` can return multiple results, you should process those results using a loop that calls `mysql_next_result()` to determine whether there are more results.

For an example that shows how to use `mysql_next_result()`, see [Section 28.2.9, “C API Handling of Multiple Statement Execution”](#).

### Return Values

| Return Value | Description                              |
|--------------|------------------------------------------|
| 0            | Successful and there are more results    |
| -1           | Successful and there are no more results |
| >0           | An error occurred                        |

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order. For example if you didn't call `mysql_use_result()` for a previous result set.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 28.2.3.47. `mysql_num_fields()`

```
unsigned int mysql_num_fields(MYSQL_RES *result)
```

To pass a `MYSQL*` argument instead, use `unsigned int mysql_field_count(MYSQL *mysql)`.

#### Description

Returns the number of columns in a result set.

Note that you can get the number of columns either from a pointer to a result set or to a connection handle. You would use the connection handle if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See [Section 28.2.14.1, “Why `mysql\_store\_result\(\)` Sometimes Returns `NULL` After `mysql\_query\(\)` Returns Success”](#).

#### Return Values

An unsigned integer representing the number of columns in a result set.

#### Errors

None.

#### Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
```

```

{
 // error
}
else // query succeeded, process any data returned by it
{
 result = mysql_store_result(&mysql);
 if (result) // there are rows
 {
 num_fields = mysql_num_fields(result);
 // retrieve rows, then call mysql_free_result(result)
 }
 else // mysql_store_result() returned nothing; should it have?
 {
 if (mysql_errno(&mysql))
 {
 fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
 }
 else if (mysql_field_count(&mysql) == 0)
 {
 // query does not return data
 // (it was not a SELECT)
 num_rows = mysql_affected_rows(&mysql);
 }
 }
}
}

```

An alternative (if you know that your query should have returned a result set) is to replace the `mysql_errno(&mysql)` call with a check whether `mysql_field_count(&mysql)` returns 0. This happens only if something went wrong.

### 28.2.3.48. `mysql_num_rows()`

```
my_ulonglong mysql_num_rows(MYSQL_RES *result)
```

#### Description

Returns the number of rows in the result set.

The use of `mysql_num_rows()` depends on whether you use `mysql_store_result()` or `mysql_use_result()` to return the result set. If you use `mysql_store_result()`, `mysql_num_rows()` may be called immediately. If you use `mysql_use_result()`, `mysql_num_rows()` does not return the correct value until all the rows in the result set have been retrieved.

`mysql_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_affected_rows()`.

#### Return Values

The number of rows in the result set.

#### Errors

None.

### 28.2.3.49. `mysql_options()`

```
int mysql_options(MYSQL *mysql, enum mysql_option option, const void *arg)
```

#### Description

Can be used to set extra connect options and affect behavior for a connection. This function may be called multiple times to set several options.

`mysql_options()` should be called after `mysql_init()` and before `mysql_connect()` or `mysql_real_connect()`.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, `arg` should point to the value of the integer.

The following list describes the possible options, their effect, and how `arg` is used for each option. Several of the options apply only when the application is linked against the `libmysqld` embedded server library and are unused for applications linked against the `libmysql` client library. For option descriptions that indicate `arg` is unused, its value is irrelevant; it is conventional to pass 0.

- `MYSQL_INIT_COMMAND` (argument type: `char *`)

Statement to execute when connecting to the MySQL server. Automatically re-executed if reconnection occurs.

- `MYSQL_OPT_COMPRESS` (argument: not used)  
Use the compressed client/server protocol.
- `MYSQL_OPT_CONNECT_TIMEOUT` (argument type: `unsigned int *`)  
Connect timeout in seconds.
- `MYSQL_OPT_GUESS_CONNECTION` (argument: not used)  
For an application linked against the `libmysqld` embedded server library, this allows the library to guess whether to use the embedded server or a remote server. “Guess” means that if the hostname is set and is not `localhost`, it uses a remote server. This behavior is the default. `MYSQL_OPT_USE_EMBEDDED_CONNECTION` and `MYSQL_OPT_USE_REMOTE_CONNECTION` can be used to override it. This option is ignored for applications linked against the `libmysqlclient` client library.
- `MYSQL_OPT_LOCAL_INFILE` (argument type: optional pointer to `unsigned int`)  
If no pointer is given or if pointer points to an `unsigned int` that has a non-zero value, the `LOAD LOCAL INFILE` statement is enabled.
- `MYSQL_OPT_NAMED_PIPE` (argument: not used)  
Use named pipes to connect to a MySQL server on Windows, if the server allows named-pipe connections.
- `MYSQL_OPT_PROTOCOL` (argument type: `unsigned int *`)  
Type of protocol to use. Should be one of the enum values of `mysql_protocol_type` defined in `mysql.h`.
- `MYSQL_OPT_READ_TIMEOUT` (argument type: `unsigned int *`)  
The timeout in seconds for attempts to read from the server. Each attempt uses this timeout value and there are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP `Close_Wait_Timeout` value of 10 minutes. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12.
- `MYSQL_OPT_RECONNECT` (argument type: `my_bool *`)  
Enable or disable automatic reconnection to the server if the connection is found to have been lost. Reconnect is off by default; this option provides a way to set reconnection behavior explicitly.  
  
Note: `mysql_real_connect()` incorrectly reset the `MYSQL_OPT_RECONNECT` option to its default value before MySQL 5.1.6. Therefore, prior to that version, if you want reconnect to be enabled for each connection, you must call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option after each call to `mysql_real_connect()`. This is not necessary as of 5.1.6: Call `mysql_options()` only before `mysql_real_connect()` as usual.
- `MYSQL_OPT_SET_CLIENT_IP` (argument type: `char *`)  
For an application linked against the `libmysqld` embedded server library (when `libmysqld` is compiled with authentication support), this means that the user is considered to have connected from the specified IP address (specified as a string) for authentication purposes. This option is ignored for applications linked against the `libmysqlclient` client library.
- `MYSQL_OPT_SSL_VERIFY_SERVER_CERT` (argument type: `my_bool *`)  
Enable or disable verification of the server's Common Name value in its certificate against the hostname used when connecting to the server. The connection is rejected if there is a mismatch. This feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default. Added in MySQL 5.1.11.
- `MYSQL_OPT_USE_EMBEDDED_CONNECTION` (argument: not used)  
For an application linked against the `libmysqld` embedded server library, this forces the use of the embedded server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.
- `MYSQL_OPT_USE_REMOTE_CONNECTION` (argument: not used)  
For an application linked against the `libmysqld` embedded server library, this forces the use of a remote server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.
- `MYSQL_OPT_USE_RESULT` (argument: not used)  
This option is unused.

- `MYSQL_OPT_WRITE_TIMEOUT` (argument type: `unsigned int *`)

The timeout in seconds for attempts to write to the server. Each attempt uses this timeout value and there are `net_retry_count` retries if necessary, so the total effective timeout value is `net_retry_count` times the option value. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12.
- `MYSQL_READ_DEFAULT_FILE` (argument type: `char *`)

Read options from the named option file instead of from `my.cnf`.
- `MYSQL_READ_DEFAULT_GROUP` (argument type: `char *`)

Read options from the named group from `my.cnf` or the file specified with `MYSQL_READ_DEFAULT_FILE`.
- `MYSQL_REPORT_DATA_TRUNCATION` (argument type: `my_bool *`)

Enable or disable reporting of data truncation errors for prepared statements via the `error` member of `MYSQL_BIND` structures. (Default: enabled.)
- `MYSQL_SECURE_AUTH` (argument type: `my_bool *`)

Whether to connect to a server that does not support the password hashing used in MySQL 4.1.1 and later.
- `MYSQL_SET_CHARSET_DIR` (argument type: `char *`)

The pathname to the directory that contains character set definition files.
- `MYSQL_SET_CHARSET_NAME` (argument type: `char *`)

The name of the character set to use as the default character set.
- `MYSQL_SHARED_MEMORY_BASE_NAME` (argument type: `char *`)

The name of the shared-memory object for communication to the server on Windows, if the server supports shared-memory connections. Should have the same value as the `--shared-memory-base-name` option used for the `mysqld` server you want to connect to.

The `client` group is always read if you use `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP`.

The specified group in the option file may contain the following options:

| Option                                          | Description                                                                                                                                             |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>character-sets-dir=path</code>            | The directory where character sets are installed.                                                                                                       |
| <code>compress</code>                           | Use the compressed client/server protocol.                                                                                                              |
| <code>connect-timeout=seconds</code>            | Connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.                                        |
| <code>database=db_name</code>                   | Connect to this database if no database was specified in the connect command.                                                                           |
| <code>debug</code>                              | Debug options.                                                                                                                                          |
| <code>default-character-set=charset_name</code> | The default character set to use.                                                                                                                       |
| <code>disable-local-infile</code>               | Disable use of <code>LOAD DATA LOCAL</code> .                                                                                                           |
| <code>host=host_name</code>                     | Default hostname.                                                                                                                                       |
| <code>init-command=stmt</code>                  | Statement to execute when connecting to MySQL server. Automatically re-executed if reconnection occurs.                                                 |
| <code>interactive-timeout=seconds</code>        | Same as specifying <code>CLIENT_INTERACTIVE</code> to <code>mysql_real_connect()</code> . See Section 28.2.3.52, “ <code>mysql_real_connect()</code> ”. |
| <code>local-infile[={0 1}]</code>               | If no argument or non-zero argument, enable use of <code>LOAD DATA LOCAL</code> ; otherwise disable.                                                    |
| <code>max_allowed_packet=bytes</code>           | Maximum size of packet that client can read from server.                                                                                                |
| <code>multi-queries, multi-results</code>       | Allow multiple result sets from multiple-statement executions or stored procedures.                                                                     |
| <code>multi-statements</code>                   | Allow the client to send multiple statements in a single string (separated by “;”).                                                                     |
| <code>password=password</code>                  | Default password.                                                                                                                                       |
| <code>pipe</code>                               | Use named pipes to connect to a MySQL server on Windows.                                                                                                |

|                                                |                                                                                                              |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>port=port_num</code>                     | Default port number.                                                                                         |
| <code>protocol={TCP SOCKET PIPE MEMORY}</code> | The protocol to use when connecting to the server.                                                           |
| <code>return-found-rows</code>                 | Tell <code>mysql_info()</code> to return found rows instead of updated rows when using <code>UPDATE</code> . |
| <code>shared-memory-base-name=name</code>      | Shared-memory name to use to connect to server.                                                              |
| <code>socket=path</code>                       | Default socket file.                                                                                         |
| <code>ssl-ca=file_name</code>                  | Certificate Authority file.                                                                                  |
| <code>ssl-capath=path</code>                   | Certificate Authority directory.                                                                             |
| <code>ssl-cert=file_name</code>                | Certificate file.                                                                                            |
| <code>ssl-cipher=cipher_list</code>            | Allowable SSL ciphers.                                                                                       |
| <code>ssl-key=file_name</code>                 | Key file.                                                                                                    |
| <code>timeout=seconds</code>                   | Like <code>connect-timeout</code> .                                                                          |
| <code>user</code>                              | Default user.                                                                                                |

`timeout` has been replaced by `connect-timeout`, but `timeout` is still supported in MySQL 5.1 for backward compatibility.

For more information about option files, see [Section 4.2.2.2, “Using Option Files”](#).

Before MySQL 5.1.18, the `arg` argument was declared as `char *`.

### Return Values

Zero for success. Non-zero if you specify an unknown option.

### Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql, MYSQL_OPT_COMPRESS, 0);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "odbc");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
 fprintf(stderr, "Failed to connect to database: Error: %s\n",
 mysql_error(&mysql));
}
```

This code requests that the client use the compressed client/server protocol and read the additional options from the `odbc` section in the `my.cnf` file.

## 28.2.3.50. `mysql_ping()`

```
int mysql_ping(MYSQL *mysql)
```

### Description

Checks whether the connection to the server is working. If the connection has gone down, an attempt to reconnect is made unless auto-reconnect is disabled.

This function can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

### Return Values

Zero if the connection to the server is alive. Non-zero if an error occurred. A non-zero return does not indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 28.2.3.51. `mysql_query()`

```
int mysql_query(MYSQL *mysql, const char *stmt_str)
```

#### Description

Executes the SQL statement pointed to by the null-terminated string `stmt_str`. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (“;”) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 28.2.9, “C API Handling of Multiple Statement Execution”](#).

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the “\0” character, which `mysql_query()` interprets as the end of the statement string.)

If you want to know whether the statement should return a result set, you can use `mysql_field_count()` to check for this. See [Section 28.2.3.22, “mysql\\_field\\_count\(\)”](#).

#### Return Values

Zero if the statement was successful. Non-zero if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 28.2.3.52. `mysql_real_connect()`

```
MYSQL *mysql_real_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd, const char *db, unsigned int port, const char *unix_socket, unsigned long client_flag)
```

#### Description

`mysql_real_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_real_connect()` must complete successfully before you can execute any other API functions that require a valid `MYSQL` connection handle structure.

The parameters are specified as follows:

- The first parameter should be the address of an existing `MYSQL` structure. Before calling `mysql_real_connect()` you must call `mysql_init()` to initialize the `MYSQL` structure. You can change a lot of connect options with the `mysql_options()` call. See [Section 28.2.3.49, “mysql\\_options\(\)”](#).
- The value of `host` may be either a hostname or an IP address. If `host` is `NULL` or the string “localhost”, a connection to the local host is assumed: For Windows, the client connects using a shared-memory connection, if the server has shared-memory connections enabled. Otherwise, TCP/IP is used. For Unix, the client connects using a Unix socket file. For local con-

nections, you can also influence the type of connection to use with the `MYSQL_OPT_PROTOCOL` or `MYSQL_OPT_NAMED_PIPE` options to `mysql_options()`. The type of connection must be supported by the server. For a `host` value of "." on Windows, the client connects using a named pipe, if the server has named-pipe connections enabled. If named-pipe connections are not enabled, an error occurs.

- The `user` parameter contains the user's MySQL login ID. If `user` is `NULL` or the empty string "", the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current username must be specified explicitly. See the MyODBC section of [Chapter 29, Connectors](#).
- The `passwd` parameter contains the password for `user`. If `passwd` is `NULL`, only entries in the `user` table for the user that have a blank (empty) password field are checked for a match. This allows the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether they have specified a password.

### Note

Do not attempt to encrypt the password before calling `mysql_real_connect()`; password encryption is handled automatically by the client API.

- The `user` and `passwd` parameters use whatever character set has been configured for the `MYSQL` object. By default, this is `latin1`, but can be changed by calling `mysql_options(mysql, MYSQL_SET_CHARSET_NAME, "charset_name")` prior to connecting.
- `db` is the database name. If `db` is not `NULL`, the connection sets the default database to this value.
- If `port` is not 0, the value is used as the port number for the TCP/IP connection. Note that the `host` parameter determines the type of the connection.
- If `unix_socket` is not `NULL`, the string specifies the socket or named pipe that should be used. Note that the `host` parameter determines the type of the connection.
- The value of `client_flag` is usually 0, but can be set to a combination of the following flags to enable certain features:

| Flag Name                            | Flag Description                                                                                                                                                                                                                                                                 |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>CLIENT_COMPRESS</code>         | Use compression protocol.                                                                                                                                                                                                                                                        |
| <code>CLIENT_FOUND_ROWS</code>       | Return the number of found (matched) rows, not the number of changed rows.                                                                                                                                                                                                       |
| <code>CLIENT_IGNORE_SIGPIPE</code>   | Prevents the client library from installing a <code>SIGPIPE</code> signal handler. This can be used to avoid conflicts with a handler that the application has already installed.                                                                                                |
| <code>CLIENT_IGNORE_SPACE</code>     | Allow spaces after function names. Makes all functions names reserved words.                                                                                                                                                                                                     |
| <code>CLIENT_INTERACTIVE</code>      | Allow <code>interactive_timeout</code> seconds (instead of <code>wait_timeout</code> seconds) of inactivity before closing the connection. The client's session <code>wait_timeout</code> variable is set to the value of the session <code>interactive_timeout</code> variable. |
| <code>CLIENT_LOCAL_FILES</code>      | Enable <code>LOAD DATA LOCAL</code> handling.                                                                                                                                                                                                                                    |
| <code>CLIENT_MULTI_RESULTS</code>    | Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This is automatically set if <code>CLIENT_MULTI_STATEMENTS</code> is set. See the note following this table for more information about this flag.       |
| <code>CLIENT_MULTI_STATEMENTS</code> | Tell the server that the client may send multiple statements in a single string (separated by ";"). If this flag is not set, multiple-statement execution is disabled. See the note following this table for more information about this flag.                                   |
| <code>CLIENT_NO_SCHEMA</code>        | Don't allow the <code>db_name.tbl_name.col_name</code> syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs.                                                                      |
| <code>CLIENT_ODBC</code>             | Unused.                                                                                                                                                                                                                                                                          |
| <code>CLIENT_SSL</code>              | Use SSL (encrypted protocol). This option should not be set by application programs; it is set internally in the client library. Instead, use <code>mysql_ssl_set()</code> before calling <code>mysql_real_connect()</code> .                                                    |

If your program uses the `CALL` SQL statement to execute stored procedures that produce result sets, you *must* set the `CLIENT_MULTI_RESULTS` flag, either explicitly, or implicitly by setting `CLIENT_MULTI_STATEMENTS` when you call `mysql_real_connect()`. This is because each such stored procedure produces multiple results: the result sets returned by statements executed within the procedure, as well as a result to indicate the call status.

If you enable `CLIENT_MULTI_STATEMENTS` or `CLIENT_MULTI_RESULTS`, you should process the result for every call to

`mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 28.2.9, “C API Handling of Multiple Statement Execution”](#).

For some parameters, it is possible to have the value taken from an option file rather than from an explicit value in the `mysql_real_connect()` call. To do this, call `mysql_options()` with the `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP` option before calling `mysql_real_connect()`. Then, in the `mysql_real_connect()` call, specify the “no-value” value for each parameter to be read from an option file:

- For `host`, specify a value of `NULL` or the empty string (`" "`).
- For `user`, specify a value of `NULL` or the empty string.
- For `passwd`, specify a value of `NULL`. (For the password, a value of the empty string in the `mysql_real_connect()` call cannot be overridden in an option file, because the empty string indicates explicitly that the MySQL account must have an empty password.)
- For `db`, specify a value of `NULL` or the empty string.
- For `port`, specify a value of 0.
- For `unix_socket`, specify a value of `NULL`.

If no value is found in an option file for a parameter, its default value is used as indicated in the descriptions given earlier in this section.

### Return Values

A `MYSQL*` connection handle if the connection was successful, `NULL` if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

### Errors

- `CR_CONN_HOST_ERROR`  
Failed to connect to the MySQL server.
- `CR_CONNECTION_ERROR`  
Failed to connect to the local MySQL server.
- `CR_IPSOCK_ERROR`  
Failed to create an IP socket.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SOCKET_CREATE_ERROR`  
Failed to create a Unix socket.
- `CR_UNKNOWN_HOST`  
Failed to find the IP address for the hostname.
- `CR_VERSION_ERROR`  
A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version.
- `CR_NAMEDPIPEOPEN_ERROR`  
Failed to create a named pipe on Windows.
- `CR_NAMEDPIPEWAIT_ERROR`  
Failed to wait for a named pipe on Windows.
- `CR_NAMEDPIPESETSTATE_ERROR`

Failed to get a pipe handler on Windows.

- `CR_SERVER_LOST`

If `connect_timeout > 0` and it took longer than `connect_timeout` seconds to connect to the server or if the server died while executing the `init-command`.

### Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql,MYSQL_READ_DEFAULT_GROUP,"your_prog_name");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
 fprintf(stderr, "Failed to connect to database: Error: %s\n",
 mysql_error(&mysql));
}
```

By using `mysql_options()` the MySQL library reads the `[client]` and `[your_prog_name]` sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some non-standard way.

Note that upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior.

### 28.2.3.53. `mysql_real_escape_string()`

```
unsigned long mysql_real_escape_string(MYSQL *mysql, char *to, const char *from, unsigned long length)
```

Note that `mysql` must be a valid, open connection. This is needed because the escaping depends on the character set in use by the server.

#### Description

This function is used to create a legal SQL string that you can use in an SQL statement. See [Section 8.1.1, “Strings”](#).

The string in `from` is encoded to an escaped SQL string, taking into account the current character set of the connection. The result is placed in `to` and a terminating null byte is appended. Characters encoded are `NUL` (ASCII 0), “`\n`”, “`\r`”, “`\`”, “`'`”, “`”`”, and Control-Z (see [Section 8.1, “Literal Values”](#)). (Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. This function quotes the other characters to make them easier to read in log files.)

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and you need room for the terminating null byte.) When `mysql_real_escape_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

If you need to change the character set of the connection, you should use the `mysql_set_character_set()` function rather than executing a `SET NAMES` (or `SET CHARACTER SET`) statement. `mysql_set_character_set()` works like `SET NAMES` but also affects the character set used by `mysql_real_escape_string()`, which `SET NAMES` does not.

### Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
*end++ = '\ ' ;
end += mysql_real_escape_string(&mysql, end,"What's this",11);
*end++ = '\ ' ;
*end++ = ',' ;
*end++ = '\ ' ;
end += mysql_real_escape_string(&mysql, end,"binary data: \0\r\n",16);
*end++ = '\ ' ;
*end++ = '\ ' ;

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
 fprintf(stderr, "Failed to insert row, Error: %s\n",
 mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a

pointer to the terminating null of the first parameter.

#### Return Values

The length of the value placed into `to`, not including the terminating null character.

#### Errors

None.

### 28.2.3.54. `mysql_real_query()`

```
int mysql_real_query(MYSQL *mysql, const char *stmt_str, unsigned long length)
```

#### Description

Executes the SQL statement pointed to by `stmt_str`, which should be a string `length` bytes long. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (“;”) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 28.2.9, “C API Handling of Multiple Statement Execution”](#).

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the “\0” character, which `mysql_query()` interprets as the end of the statement string.) In addition, `mysql_real_query()` is faster than `mysql_query()` because it does not call `strlen()` on the statement string.

If you want to know whether the statement should return a result set, you can use `mysql_field_count()` to check for this. See [Section 28.2.3.22, “mysql\\_field\\_count\(\)”](#).

#### Return Values

Zero if the statement was successful. Non-zero if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 28.2.3.55. `mysql_refresh()`

```
int mysql_refresh(MYSQL *mysql, unsigned int options)
```

#### Description

This function flushes tables or caches, or resets replication server information. The connected user must have the `RELOAD` privilege.

The `options` argument is a bit mask composed from any combination of the following values. Multiple values can be OR'ed together to perform multiple operations with a single call.

- `REFRESH_GRANT`  
Refresh the grant tables, like `FLUSH PRIVILEGES`.
- `REFRESH_LOG`  
Flush the logs, like `FLUSH LOGS`.

- [REFRESH\\_TABLES](#)  
Flush the table cache, like [FLUSH TABLES](#).
- [REFRESH\\_HOSTS](#)  
Flush the host cache, like [FLUSH HOSTS](#).
- [REFRESH\\_STATUS](#)  
Reset status variables, like [FLUSH STATUS](#).
- [REFRESH\\_THREADS](#)  
Flush the thread cache.
- [REFRESH\\_SLAVE](#)  
On a slave replication server, reset the master server information and restart the slave, like [RESET SLAVE](#).
- [REFRESH\\_MASTER](#)  
On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like [RESET MASTER](#).

**Return Values**

Zero for success. Non-zero if an error occurred.

**Errors**

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST](#)  
The connection to the server was lost during the query.
- [CR\\_UNKNOWN\\_ERROR](#)  
An unknown error occurred.

**28.2.3.56. [mysql\\_reload\(\)](#)**

```
int mysql_reload(MYSQL *mysql)
```

**Description**

Asks the MySQL server to reload the grant tables. The connected user must have the [RELOAD](#) privilege.

This function is deprecated. It is preferable to use [mysql\\_query\(\)](#) to issue an SQL [FLUSH PRIVILEGES](#) statement instead.

**Return Values**

Zero for success. Non-zero if an error occurred.

**Errors**

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 28.2.3.57. `mysql_rollback()`

```
my_bool mysql_rollback(MYSQL *mysql)
```

#### Description

Rolls back the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

#### Return Values

Zero if successful. Non-zero if an error occurred.

#### Errors

None.

### 28.2.3.58. `mysql_row_seek()`

```
MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET offset)
```

#### Description

Sets the row cursor to an arbitrary row in a query result set. The `offset` value is a row offset that should be a value returned from `mysql_row_tell()` or from `mysql_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_row_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

#### Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_row_seek()`.

#### Errors

None.

### 28.2.3.59. `mysql_row_tell()`

```
MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)
```

#### Description

Returns the current position of the row cursor for the last `mysql_fetch_row()`. This value can be used as an argument to `mysql_row_seek()`.

You should use `mysql_row_tell()` only after `mysql_store_result()`, not after `mysql_use_result()`.

#### Return Values

The current offset of the row cursor.

#### Errors

None.

### 28.2.3.60. `mysql_select_db()`

```
int mysql_select_db(MYSQL *mysql, const char *db)
```

#### Description

Causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_select_db()` fails unless the connected user can be authenticated as having permission to use the database.

#### Return Values

Zero for success. Non-zero if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 28.2.3.61. `mysql_set_character_set()`

```
int mysql_set_character_set(MYSQL *mysql, const char *csname)
```

#### Description

This function is used to set the default character set for the current connection. The string `csname` specifies a valid character set name. The connection collation becomes the default collation of the character set. This function works like the `SET NAMES` statement, but also sets the value of `mysql->charset`, and thus affects the character set used by `mysql_real_escape_string()`

#### Return Values

Zero for success. Non-zero if an error occurred.

#### Example

```
MYSQL mysql;
mysql_init(&mysql);
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
 fprintf(stderr, "Failed to connect to database: Error: %s\n",
 mysql_error(&mysql));
}
if (!mysql_set_character_set(&mysql, "utf8"))
{
 printf("New client character set: %s\n",
 mysql_character_set_name(&mysql));
}
```

### 28.2.3.62. `mysql_set_local_infile_default()`

```
void mysql_set_local_infile_default(MYSQL *mysql);
```

#### Description

Sets the `LOAD LOCAL DATA INFILE` handler callback functions to the defaults used internally by the C client library. The lib-

rary calls this function automatically if `mysql_set_local_infile_handler()` has not been called or does not supply valid functions for each of its callbacks.

The `mysql_set_local_infile_default()` function was added in MySQL 4.1.2.

### Return Values

None.

### Errors

None.

## 28.2.3.63. `mysql_set_local_infile_handler()`

```
void mysql_set_local_infile_handler(MYSQL *mysql, int (*local_infile_init)(void **,
const char *, void *), int (*local_infile_read)(void *, char *, unsigned int), void
(*local_infile_end)(void *), int (*local_infile_error)(void *, char*, unsigned int),
void *userdata);
```

### Description

This function installs callbacks to be used during the execution of `LOAD DATA LOCAL INFILE` statements. It enables application programs to exert control over local (client-side) data file reading. The arguments are the connection handler, a set of pointers to callback functions, and a pointer to a data area that the callbacks can use to share information.

To use `mysql_set_local_infile_handler()`, you must write the following callback functions:

```
int
local_infile_init(void **ptr, const char *filename, void *userdata);
```

The initialization function. This is called once to do any setup necessary, open the data file, allocate data structures, and so forth. The first `void**` argument is a pointer to a pointer. You can set the pointer (that is, `*ptr`) to a value that will be passed to each of the other callbacks (as a `void*`). The callbacks can use this pointed-to value to maintain state information. The `userdata` argument is the same value that is passed to `mysql_set_local_infile_handler()`.

The initialization function should return zero for success, non-zero for an error.

```
int
local_infile_read(void *ptr, char *buf, unsigned int buf_len);
```

The data-reading function. This is called repeatedly to read the data file. `buf` points to the buffer where the read data should be stored, and `buf_len` is the maximum number of bytes that the callback can read and store in the buffer. (It can read fewer bytes, but should not read more.)

The return value is the number of bytes read, or zero when no more data could be read (this indicates EOF). Return a value less than zero if an error occurs.

```
void
local_infile_end(void *ptr)
```

The termination function. This is called once after `local_infile_read()` has returned zero (EOF) or an error. This function should deallocate any memory allocated by `local_infile_init()` and perform any other cleanup necessary. It is invoked even if the initialization function returns an error.

```
int
local_infile_error(void *ptr,
char *error_msg,
unsigned int error_msg_len);
```

The error-handling function. This is called to get a textual error message to return to the user in case any of your other functions returns an error. `error_msg` points to the buffer into which the message should be written, and `error_msg_len` is the length of the buffer. The message should be written as a null-terminated string, so the message can be at most `error_msg_len-1` bytes long.

The return value is the error number.

Typically, the other callbacks store the error message in the data structure pointed to by `ptr`, so that `local_infile_error()` can copy the message from there into `error_msg`.

After calling `mysql_set_local_infile_handler()` in your C code and passing pointers to your callback functions, you

can then issue a `LOAD DATA LOCAL INFILE` statement (for example, by using `mysql_query()`). The client library automatically invokes your callbacks. The filename specified in `LOAD DATA LOCAL INFILE` will be passed as the second parameter to the `local_infile_init()` callback.

The `mysql_set_local_infile_handler()` function was added in MySQL 4.1.2.

#### Return Values

None.

#### Errors

None.

### 28.2.3.64. `mysql_set_server_option()`

```
int mysql_set_server_option(MYSQL *mysql, enum enum_mysql_set_option option)
```

#### Description

Enables or disables an option for the connection. `option` can have one of the following values:

|                                                |                                    |
|------------------------------------------------|------------------------------------|
| <code>MYSQL_OPTION_MULTI_STATEMENTS_ON</code>  | Enable multiple-statement support  |
| <code>MYSQL_OPTION_MULTI_STATEMENTS_OFF</code> | Disable multiple-statement support |

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 28.2.9, “C API Handling of Multiple Statement Execution”](#).

Enabling multiple-statement support with `MYSQL_OPTION_MULTI_STATEMENTS_ON` does not have quite the same effect as enabling it by passing the `CLIENT_MULTI_STATEMENTS` flag to `mysql_real_connect()`: `CLIENT_MULTI_STATEMENTS` also enables `CLIENT_MULTI_RESULTS`. If you are using the `CALL` SQL statement in your programs, multiple-result support must be enabled; this means that `MYSQL_OPTION_MULTI_STATEMENTS_ON` by itself is insufficient to allow the use of `CALL`.

#### Return Values

Zero for success. Non-zero if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`**  
 Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`**  
 The MySQL server has gone away.
- `CR_SERVER_LOST`**  
 The connection to the server was lost during the query.
- `ER_UNKNOWN_COM_ERROR`**  
 The server didn't support `mysql_set_server_option()` (which is the case that the server is older than 4.1.1) or the server didn't support the option one tried to set.

### 28.2.3.65. `mysql_shutdown()`

```
int mysql_shutdown(MYSQL *mysql, enum mysql_enum_shutdown_level shutdown_level)
```

#### Description

Asks the database server to shut down. The connected user must have `SHUTDOWN` privileges. MySQL 5.1 servers support only one type of shutdown; `shutdown_level` must be equal to `SHUTDOWN_DEFAULT`. Additional shutdown levels are planned to make it possible to choose the desired level. Dynamically linked executables which have been compiled with older versions of the `libmysqlclient` headers and call `mysql_shutdown()` need to be used with the old `libmysqlclient` dynamic library.

The shutdown process is described in [Section 5.1.10, “The Shutdown Process”](#).

### Return Values

Zero for success. Non-zero if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

## 28.2.3.66. `mysql_sqlstate()`

```
const char *mysql_sqlstate(MYSQL *mysql)
```

### Description

Returns a null-terminated string containing the SQLSTATE error code for the most recently executed SQL statement. The error code consists of five characters. '00000' means “no error”. The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix B, Errors, Error Codes, and Common Problems](#).

SQLSTATE values returned by `mysql_sqlstate()` differ from MySQL-specific error numbers returned by `mysql_errno()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and '42S02' is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Not all MySQL error numbers are mapped to SQLSTATE error codes. The value 'HY000' (general error) is used for unmapped error numbers.

If you call `mysql_sqlstate()` after `mysql_real_connect()` fails, `mysql_sqlstate()` might not return a useful value. For example, this happens if a host is blocked by the server and the connection is closed without any SQLSTATE value being sent to the client.

### Return Values

A null-terminated character string containing the SQLSTATE error code.

### See Also

See [Section 28.2.3.14, “mysql\\_errno\(\)”](#), [Section 28.2.3.15, “mysql\\_error\(\)”](#), and [Section 28.2.7.26, “mysql\\_stmt\\_sqlstate\(\)”](#).

## 28.2.3.67. `mysql_ssl_set()`

```
my_bool mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert, const char *ca,
const char *capath, const char *cipher)
```

### Description

`mysql_ssl_set()` is used for establishing secure connections using SSL. It must be called before `mysql_real_connect()`.

`mysql_ssl_set()` does nothing unless OpenSSL support is enabled in the client library.

`mysql` is the connection handler returned from `mysql_init()`. The other parameters are specified as follows:

- `key` is the pathname to the key file.
- `cert` is the pathname to the certificate file.
- `ca` is the pathname to the certificate authority file.
- `capath` is the pathname to a directory that contains trusted SSL CA certificates in pem format.
- `cipher` is a list of allowable ciphers to use for SSL encryption.

Any unused SSL parameters may be given as `NULL`.

#### Return Values

This function always returns 0. If SSL setup is incorrect, `mysql_real_connect()` returns an error when you attempt to connect.

### 28.2.3.68. `mysql_stat()`

```
const char *mysql_stat(MYSQL *mysql)
```

#### Description

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

#### Return Values

A character string describing the server status. `NULL` if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 28.2.3.69. `mysql_store_result()`

```
MYSQL_RES *mysql_store_result(MYSQL *mysql)
```

#### Description

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully retrieves data (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

You don't have to call `mysql_store_result()` or `mysql_use_result()` for other statements, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect whether the statement has a result set by checking whether `mysql_store_result()` returns a non-zero value (more about this later on).

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For

an example, see [Section 28.2.9, “C API Handling of Multiple Statement Execution”](#).

If you want to know whether a statement should return a result set, you can use `mysql_field_count()` to check for this. See [Section 28.2.3.22, “mysql\\_field\\_count\(\)”](#).

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns a null pointer if the statement didn't return a result set (for example, if it was an `INSERT` statement).

`mysql_store_result()` also returns a null pointer if reading of the result set failed. You can check whether an error occurred by checking whether `mysql_error()` returns a non-empty string, `mysql_errno()` returns non-zero, or `mysql_field_count()` returns zero.

An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

After you have called `mysql_store_result()` and gotten back a result that isn't a null pointer, you can call `mysql_num_rows()` to find out how many rows are in the result set.

You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

See [Section 28.2.14.1, “Why mysql\\_store\\_result\(\) Sometimes Returns NULL After mysql\\_query\(\) Returns Success”](#).

### Return Values

A `MYSQL_RES` result structure with the results. `NULL` (0) if an error occurred.

### Errors

`mysql_store_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

## 28.2.3.70. `mysql_thread_id()`

```
unsigned long mysql_thread_id(MYSQL *mysql)
```

### Description

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

### Return Values

The thread ID of the current connection.

### Errors

None.

### 28.2.3.71. `mysql_use_result()`

```
MYSQL_RES *mysql_use_result(MYSQL *mysql)
```

#### Description

You must call `mysql_store_result()` or `mysql_use_result()` for every query that successfully retrieves data (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`).

`mysql_use_result()` initiates a result set retrieval but does not actually read the result set into the client like `mysql_store_result()` does. Instead, each row must be retrieved individually by making calls to `mysql_fetch_row()`. This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than `mysql_store_result()`. The client allocates memory only for the current row and a communication buffer that may grow up to `max_allowed_packet` bytes.

On the other hand, you shouldn't use `mysql_use_result()` if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a `^S` (stop scroll). This ties up the server and prevent other threads from updating any tables from which the data is being fetched.

When using `mysql_use_result()`, you must execute `mysql_fetch_row()` until a `NULL` value is returned, otherwise, the unfetched rows are returned as part of the result set for your next query. The C API gives the error `Commands out of sync; you can't run this command now` if you forget to do this!

You may not use `mysql_data_seek()`, `mysql_row_seek()`, `mysql_row_tell()`, `mysql_num_rows()`, or `mysql_affected_rows()` with a result returned from `mysql_use_result()`, nor may you issue other queries until `mysql_use_result()` has finished. (However, after you have fetched all the rows, `mysql_num_rows()` accurately returns the number of rows fetched.)

You must call `mysql_free_result()` once you are done with the result set.

When using the `libmysqld` embedded server, the memory benefits are essentially lost because memory usage incrementally increases with each row retrieved until `mysql_free_result()` is called.

#### Return Values

A `MYSQL_RES` result structure. `NULL` if an error occurred.

#### Errors

`mysql_use_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 28.2.3.72. `mysql_warning_count()`

```
unsigned int mysql_warning_count(MYSQL *mysql)
```

#### Description

Returns the number of warnings generated during execution of the previous SQL statement.

**Return Values**

The warning count.

**Errors**

None.

**28.2.4. C API Prepared Statements**

The MySQL client/server protocol provides for the use of prepared statements. This capability uses the `MYSQL_STMT` statement handler data structure returned by the `mysql_stmt_init()` initialization function. Prepared execution is an efficient way to execute a statement more than once. The statement is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the statement handle returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Prepared statements might not provide a performance increase in some situations. For best results, test your application both with prepared and non-prepared statements and choose whichever yields best performance.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

The following statements can be used as prepared statements: `CREATE TABLE`, `DELETE`, `DO`, `INSERT`, `REPLACE`, `SELECT`, `SET`, `UPDATE`, and most `SHOW` statements.

As of MySQL 5.1.10, the following additional statements are supported:

```
ANALYZE TABLE
OPTIMIZE TABLE
REPAIR TABLE
```

As of MySQL 5.1.12, the following additional statements are supported:

```
CACHE INDEX
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
{CREATE | RENAME | DROP} DATABASE
{CREATE | RENAME | DROP} USER
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
 | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}
GRANT
REVOKE
KILL
LOAD INDEX INTO CACHE
RESET {MASTER | SLAVE | QUERY CACHE}
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {AUTHORS | CONTRIBUTORS | WARNINGS | ERRORS}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
INSTALL PLUGIN
UNINSTALL PLUGIN
```

Other statements are not yet supported in MySQL 5.1.

**MySQL Enterprise**

MySQL Enterprise subscribers will find more information about using prepared statements in the Knowledge Base article, [How can I create server-side prepared statements?](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

**28.2.5. C API Prepared Statement Data types**

Prepared statements use several data structures:

- To prepare a statement, pass the statement string to `mysql_stmt_init()`, which returns a pointer to a `MYSQL_STMT` data structure.
- To provide input parameters for a prepared statement, set up `MYSQL_BIND` structures and pass them to

`mysql_stmt_bind_param()`. To receive output column values, set up `MYSQL_BIND` structures and pass them to `mysql_stmt_bind_result()`.

- The `MYSQL_TIME` structure is used to transfer temporal data in both directions.

The following discussion describes the prepared statement data types in detail.

- `MYSQL_STMT`

This structure represents a prepared statement. A statement is created by calling `mysql_stmt_init()`, which returns a statement handle (that is, a pointer to a `MYSQL_STMT`). The handle is used for all subsequent operations with the statement until you close it with `mysql_stmt_close()`, at which point the handle becomes invalid.

The `MYSQL_STMT` structure has no members that are intended for application use. Also, you should not try to make a copy of a `MYSQL_STMT` structure. There is no guarantee that such a copy will be usable.

Multiple statement handles can be associated with a single connection. The limit on the number of handles depends on the available system resources.

- `MYSQL_BIND`

This structure is used both for statement input (data values sent to the server) and output (result values returned from the server):

- For input, `MYSQL_BIND` is used with `mysql_stmt_bind_param()` to bind parameter data values to buffers for use by `mysql_stmt_execute()`.
- For output, `MYSQL_BIND` is used with `mysql_stmt_bind_result()` to bind result set buffers for use in fetching rows with `mysql_stmt_fetch()`.

To use a `MYSQL_BIND` structure, you should zero its contents to initialize it, and then set its members appropriately. For example, to declare and initialize an array of three `MYSQL_BIND` structures, use this code:

```
MYSQL_BIND bind[3];
memset(bind, 0, sizeof(bind));
```

The `MYSQL_BIND` structure contains the following members for use by application programs. For several of the members, the manner of use depends on whether the structure is used for input or output.

- `enum enum_field_types buffer_type`

The type of the buffer. This member indicates the data type of the C language variable that you are binding to the statement parameter. The allowable `buffer_type` values are listed later in this section. For input, `buffer_type` indicates the type of the variable containing the value that you will send to the server. For output, it indicates the type of the variable into which you want a value received from the server to be stored.

- `void *buffer`

A pointer to the buffer to be used for data transfer. This is the address of a variable.

For input, `buffer` is a pointer to the variable in which a statement parameter's data value is stored. When you call `mysql_stmt_execute()`, MySQL takes the value that you have stored in the variable and uses it in place of the corresponding parameter marker in the statement.

For output, `buffer` is a pointer to the variable in which to return a result set column value. When you call `mysql_stmt_fetch()`, MySQL returns a column value and stores it in this variable. You can access the value when the call returns.

To minimize the need for MySQL to perform type conversions between C language values on the client side and SQL values on the server side, use variables that have types similar to those of the corresponding SQL values. For numeric data types, `buffer` should point to a variable of the proper numeric C type. (For `char` or integer variables, you should also indicate whether the variable has the `unsigned` attribute by setting the `is_unsigned` member, described later in this list.) For character (non-binary) and binary string data types, `buffer` should point to a character buffer. For date and time data types, `buffer` should point to a `MYSQL_TIME` structure.

See the notes about type conversions later in the section.

- `unsigned long buffer_length`

The actual size of `*buffer` in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the `buffer_length` value specifies the length of `*buffer` when used with `mysql_stmt_bind_param()` to specify input values, or the maximum number of output data bytes that can be fetched into the buffer when used with `mysql_stmt_bind_result()`.

- `unsigned long *length`

A pointer to an `unsigned long` variable that indicates the actual number of bytes of data stored in `*buffer`. `length` is used for character or binary C data.

For input parameter data binding, `length` points to an `unsigned long` variable that indicates the actual length of the parameter value stored in `*buffer`; this is used by `mysql_stmt_execute()`.

For output value binding, the return value of `mysql_stmt_fetch()` determines the interpretation of the length:

- If `mysql_stmt_fetch()` returns 0, `*length` indicates the actual length of the parameter value.
- If `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED`, `*length` indicates the non-truncated length of the parameter value. In this case, the minimum of `*length` and `buffer_length` indicates the actual length of the value.

`length` is ignored for numeric and temporal data types because the length of the data value is determined by the `buffer_type` value.

If you need to be able to determine the length of a returned value before fetching it with `mysql_stmt_fetch()`, see [Section 28.2.7.11, “mysql\\_stmt\\_fetch\(\)”](#), for some strategies.

- `my_bool *is_null`

This member points to a `my_bool` variable that is true if a value is `NULL`, false if it is not `NULL`. For input, set `*is_null` to true to indicate that you are passing a `NULL` value as a statement parameter.

The reason that `is_null` is not a boolean scalar but is instead a *pointer* to a boolean scalar is to provide flexibility in how you specify `NULL` values:

- If your data values are always `NULL`, use `MYSQL_TYPE_NULL` as the `buffer_type` value when you bind the column. The other members do not matter.
- If your data values are always `NOT NULL`, set the other members appropriately for the variable you are binding, and set `is_null = (my_bool*) 0`.
- In all other cases, set the other members appropriately, and set `is_null` to the address of a `my_bool` variable. Set that variable's value to true or false appropriately between executions to indicate whether data values are `NULL` or `NOT NULL`, respectively.

For output, the value pointed to by `is_null` is set to true after you fetch a row if the result set column value returned from the statement is `NULL`.

- `my_bool is_unsigned`

This member is used for C variables with data types that can be `unsigned` (`char`, `short int`, `int`, `long long int`). Set `is_unsigned` to true if the variable pointed to by `buffer` is `unsigned` and false otherwise. For example, if you bind a `signed char` variable to `buffer`, specify a type code of `MYSQL_TYPE_TINY` and set `is_unsigned` to false. If you bind an `unsigned char` instead, the type code is the same but `is_unsigned` should be true. (For `char`, it is not defined whether it is signed or unsigned, so it is best to be explicit about signedness by using `signed char` or `unsigned char`.)

`is_unsigned` applies only to the C language variable on the client side. It indicates nothing about the signedness of the corresponding SQL value on the server side. For example, if you use an `int` variable to supply a value for a `BIGINT UNSIGNED` column, `is_unsigned` should be false because `int` is a signed type. If you use an `unsigned int` variable to supply a value for a `BIGINT` column, `is_unsigned` should be true because `unsigned int` is an unsigned type. MySQL performs the proper conversion between signed and unsigned values in both directions, although a warning occurs if truncation results.

- `my_bool *error`

For output, set this member to point to a `my_bool` variable to have truncation information for the parameter stored there after a row fetching operation. (Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.) When truncation reporting is enabled,

`mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED` and `*error` is true in the `MYSQL_BIND` structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column.

- `MYSQL_TIME`

This structure is used to send and receive `DATE`, `TIME`, `DATETIME`, and `TIMESTAMP` data directly to and from the server. Set the `buffer_type` member of a `MYSQL_BIND` structure to one of the temporal types (`MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATE`, `MYSQL_TYPE_DATETIME`, `MYSQL_TYPE_TIMESTAMP`), and set the `buffer` member to point to a `MYSQL_TIME` structure.

The `MYSQL_TIME` structure contains the members listed in the following table.

| Member                                 | Description                                                         |
|----------------------------------------|---------------------------------------------------------------------|
| <code>unsigned int year</code>         | The year                                                            |
| <code>unsigned int month</code>        | The month of the year                                               |
| <code>unsigned int day</code>          | The day of the month                                                |
| <code>unsigned int hour</code>         | The hour of the day                                                 |
| <code>unsigned int minute</code>       | The minute of the hour                                              |
| <code>unsigned int second</code>       | The second of the minute                                            |
| <code>my_bool neg</code>               | A boolean flag to indicate whether the time is negative             |
| <code>unsigned long second_part</code> | The fractional part of the second in microseconds; currently unused |

Only those parts of a `MYSQL_TIME` structure that apply to a given type of temporal value are used. The `year`, `month`, and `day` elements are used for `DATE`, `DATETIME`, and `TIMESTAMP` values. The `hour`, `minute`, and `second` elements are used for `TIME`, `DATETIME`, and `TIMESTAMP` values. See [Section 28.2.10, “C API Handling of Date and Time Values”](#).

The following table shows the allowable values that may be specified in the `buffer_type` member of `MYSQL_BIND` structures for input values. The value should be chosen according to the data type of the C language variable that you are binding. If the variable is `unsigned`, you should also set the `is_unsigned` member to true. The table shows the C variable types that you can use, the corresponding type codes, and the SQL data types for which the supplied value can be used without conversion.

| Input Variable C Type      | <code>buffer_type</code> Value                       | SQL Type of Destination Value                                    |
|----------------------------|------------------------------------------------------|------------------------------------------------------------------|
| <code>signed char</code>   | <code>MYSQL_TYPE_TINY</code>                         | <code>TINYINT</code>                                             |
| <code>short int</code>     | <code>MYSQL_TYPE_SHORT</code>                        | <code>SMALLINT</code>                                            |
| <code>int</code>           | <code>MYSQL_TYPE_LONG</code>                         | <code>INT</code>                                                 |
| <code>long long int</code> | <code>MYSQL_TYPE_LONGLONG</code>                     | <code>BIGINT</code>                                              |
| <code>float</code>         | <code>MYSQL_TYPE_FLOAT</code>                        | <code>FLOAT</code>                                               |
| <code>double</code>        | <code>MYSQL_TYPE_DOUBLE</code>                       | <code>DOUBLE</code>                                              |
| <code>MYSQL_TIME</code>    | <code>MYSQL_TYPE_TIME</code>                         | <code>TIME</code>                                                |
| <code>MYSQL_TIME</code>    | <code>MYSQL_TYPE_DATE</code>                         | <code>DATE</code>                                                |
| <code>MYSQL_TIME</code>    | <code>MYSQL_TYPE_DATETIME</code>                     | <code>DATETIME</code>                                            |
| <code>MYSQL_TIME</code>    | <code>MYSQL_TYPE_TIMESTAMP</code>                    | <code>TIMESTAMP</code>                                           |
| <code>char[]</code>        | <code>MYSQL_TYPE_STRING</code> (for non-binary data) | <code>TEXT</code> , <code>CHAR</code> , <code>VARCHAR</code>     |
| <code>char[]</code>        | <code>MYSQL_TYPE_BLOB</code> (for binary data)       | <code>BLOB</code> , <code>BINARY</code> , <code>VARBINARY</code> |
|                            | <code>MYSQL_TYPE_NULL</code>                         | <code>NULL</code>                                                |

The use of `MYSQL_TYPE_NULL` is described earlier in connection with the `is_null` member.

The following table shows the allowable values that may be specified in the `buffer_type` member of `MYSQL_BIND` structures for output values. The value should be chosen according to the data type of the C language variable that you are binding. If the variable is `unsigned`, you should also set the `is_unsigned` member to true. The table shows the SQL types of received values, the corresponding type code that such values have in result set metadata, and the recommended C language data types to bind to the `MYSQL_BIND` structure to receive the SQL values without conversion.

If there is a mismatch between the C variable type on the client side and the corresponding SQL value on the server side, MySQL performs implicit type conversions in both directions.

| SQL Type of Received Value | buffer_type Value      | Output Variable C Type |
|----------------------------|------------------------|------------------------|
| TINYINT                    | MYSQL_TYPE_TINY        | signed char            |
| SMALLINT                   | MYSQL_TYPE_SHORT       | short int              |
| MEDIUMINT                  | MYSQL_TYPE_INT24       | int                    |
| INT                        | MYSQL_TYPE_LONG        | int                    |
| BIGINT                     | MYSQL_TYPE_LONGLONG    | long long int          |
| FLOAT                      | MYSQL_TYPE_FLOAT       | float                  |
| DOUBLE                     | MYSQL_TYPE_DOUBLE      | double                 |
| DECIMAL                    | MYSQL_TYPE_NEWDECIMAL  | char[ ]                |
| YEAR                       | MYSQL_TYPE_SHORT       | short int              |
| TIME                       | MYSQL_TYPE_TIME        | MYSQL_TIME             |
| DATE                       | MYSQL_TYPE_DATE        | MYSQL_TIME             |
| DATETIME                   | MYSQL_TYPE_DATETIME    | MYSQL_TIME             |
| TIMESTAMP                  | MYSQL_TYPE_TIMESTAMP   | MYSQL_TIME             |
| CHAR, BINARY               | MYSQL_TYPE_STRING      | char[ ]                |
| VARCHAR, VARBINARY         | MYSQL_TYPE_VAR_STRING  | char[ ]                |
| TINYBLOB, TINYTEXT         | MYSQL_TYPE_TINY_BLOB   | char[ ]                |
| BLOB, TEXT                 | MYSQL_TYPE_BLOB        | char[ ]                |
| MEDIUMBLOB, MEDIUMTEXT     | MYSQL_TYPE_MEDIUM_BLOB | char[ ]                |
| LONGBLOB, LONGTEXT         | MYSQL_TYPE_LONG_BLOB   | char[ ]                |
| BIT                        | MYSQL_TYPE_BIT         | char[ ]                |

MySQL knows the type code for the SQL value on the server side. The `buffer_type` value indicates the MySQL type code of the C variable that holds the value on the client side. The two codes together tell MySQL what conversion must be performed, if any. Here are some examples:

- If you use `MYSQL_TYPE_LONG` with an `int` variable to pass an integer value to the server that is to be stored into a `FLOAT` column, MySQL converts the value to floating-point format before storing it.
- If you fetch a SQL `MEDIUMINT` column value, but specify a `buffer_type` value of `MYSQL_TYPE_LONGLONG` and use a C variable of type `long long int` as the destination buffer, MySQL will convert the `MEDIUMINT` value (which requires less than 8 bytes) for storage into the `long long int` (an 8-byte variable).
- If you fetch a numeric column with a value of 255 into a `char[4]` character array and specify a `buffer_type` value of `MYSQL_TYPE_STRING`, the resulting value in the array will be a 4-byte string containing `'255\0'`.
- `DECIMAL` values are returned as strings, which is why the corresponding C type is `char[ ]`. `DECIMAL` values returned by the server correspond to the string representation of the original server-side value. For example, `12.345` is returned to the client as `'12.345'`. If you specify `MYSQL_TYPE_NEWDECIMAL` and bind a string buffer to the `MYSQL_BIND` structure, `mysql_stmt_fetch()` stores the value in the buffer without conversion. If instead you specify a numeric variable and type code, `mysql_stmt_fetch()` converts the string-format `DECIMAL` value to numeric form.
- For the `MYSQL_TYPE_BIT` type code, `BIT` values are returned into a string buffer (thus, the corresponding C type is `char[ ]` here, too). The value represents a bit string that requires interpretation on the client side. To return the value as a type that is easier to deal with, you can cause the value to be cast to integer using either of the following types of expressions:

```
SELECT bit_col + 0 FROM t
SELECT CAST(bit_col AS UNSIGNED) FROM t
```

To retrieve the value, bind an integer variable large enough to hold the value and specify the appropriate corresponding integer type code.

Before binding variables to the `MYSQL_BIND` structures that are to be used for fetching column values, you can check the type codes for each column of the result set. This might be desirable if you want to determine which variable types would be best to use to avoid type conversions. To get the type codes, call `mysql_stmt_result_metadata()` after executing the prepared state-

ment with `mysql_stmt_execute()`. The metadata provides access to the type codes for the result set as described in [Section 28.2.7.22](#), “`mysql_stmt_result_metadata()`”, and [Section 28.2.1](#), “C API Data Types”.

If you cause the `max_length` member of the `MYSQL_FIELD` column metadata structures to be set (by calling `mysql_stmt_attr_set()`), be aware that the `max_length` values for the result set indicate the lengths of the longest string representation of the result values, not the lengths of the binary representation. That is, `max_length` does not necessarily correspond to the size of the buffers needed to fetch the values with the binary protocol used for prepared statements. The size of the buffers should be chosen according to the types of the variables into which you fetch the values.

For input character (non-binary) string data (indicated by `MYSQL_TYPE_STRING`), the value is assumed to be in the character set indicated by the `character_set_client` system variable. If the value is stored into a column with a different character set, the appropriate conversion to that character set occurs. For input binary string data (indicated by `MYSQL_TYPE_BLOB`), the value is treated as having the `binary` character set; that is, it is treated as a byte string and no conversion occurs.

To determine whether output string values in a result set returned from the server contain binary or non-binary data, check whether the `charsetnr` value of the result set metadata is 63 (see [Section 28.2.1](#), “C API Data Types”). If so, the character set is `binary`, which indicates binary rather than non-binary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

As of MySQL 5.1.25, metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 12.7.1](#), “Automatic Prepared Statement Repreparation”.

## 28.2.6. C API Prepared Statement Function Overview

The functions available for prepared statement processing are summarized here and described in greater detail in a later section. See [Section 28.2.7](#), “C API Prepared Statement Function Descriptions”.

| Function                                  | Description                                                                                                                                       |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mysql_stmt_affected_rows()</code>   | Returns the number of rows changed, deleted, or inserted by prepared <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> statement |
| <code>mysql_stmt_attr_get()</code>        | Get value of an attribute for a prepared statement                                                                                                |
| <code>mysql_stmt_attr_set()</code>        | Sets an attribute for a prepared statement                                                                                                        |
| <code>mysql_stmt_bind_param()</code>      | Associates application data buffers with the parameter markers in a prepared SQL statement                                                        |
| <code>mysql_stmt_bind_result()</code>     | Associates application data buffers with columns in the result set                                                                                |
| <code>mysql_stmt_close()</code>           | Frees memory used by prepared statement                                                                                                           |
| <code>mysql_stmt_data_seek()</code>       | Seeks to an arbitrary row number in a statement result set                                                                                        |
| <code>mysql_stmt_errno()</code>           | Returns the error number for the last statement execution                                                                                         |
| <code>mysql_stmt_error()</code>           | Returns the error message for the last statement execution                                                                                        |
| <code>mysql_stmt_execute()</code>         | Executes the prepared statement                                                                                                                   |
| <code>mysql_stmt_fetch()</code>           | Fetches the next row of data from the result set and returns data for all bound columns                                                           |
| <code>mysql_stmt_fetch_column()</code>    | Fetch data for one column of the current row of the result set                                                                                    |
| <code>mysql_stmt_field_count()</code>     | Returns the number of result columns for the most recent statement                                                                                |
| <code>mysql_stmt_free_result()</code>     | Free the resources allocated to the statement handle                                                                                              |
| <code>mysql_stmt_init()</code>            | Allocates memory for <code>MYSQL_STMT</code> structure and initializes it                                                                         |
| <code>mysql_stmt_insert_id()</code>       | Returns the ID generated for an <code>AUTO_INCREMENT</code> column by prepared statement                                                          |
| <code>mysql_stmt_num_rows()</code>        | Returns total row count from the buffered statement result set                                                                                    |
| <code>mysql_stmt_param_count()</code>     | Returns the number of parameters in a prepared SQL statement                                                                                      |
| <code>mysql_stmt_param_metadata()</code>  | (Return parameter metadata in the form of a result set.) Currently, this function does nothing                                                    |
| <code>mysql_stmt_prepare()</code>         | Prepares an SQL string for execution                                                                                                              |
| <code>mysql_stmt_reset()</code>           | Reset the statement buffers in the server                                                                                                         |
| <code>mysql_stmt_result_metadata()</code> | Returns prepared statement metadata in the form of a result set                                                                                   |
| <code>mysql_stmt_row_seek()</code>        | Seeks to a row offset in a statement result set, using value returned from <code>mysql_stmt_row_tell()</code>                                     |
| <code>mysql_stmt_row_tell()</code>        | Returns the statement row cursor position                                                                                                         |
| <code>mysql_stmt_send_long_data()</code>  | Sends long data in chunks to server                                                                                                               |

|                                        |                                                                  |
|----------------------------------------|------------------------------------------------------------------|
| <code>mysql_stmt_sqlstate()</code>     | Returns the SQLSTATE error code for the last statement execution |
| <code>mysql_stmt_store_result()</code> | Retrieves the complete result set to the client                  |

Call `mysql_stmt_init()` to create a statement handle, then `mysql_stmt_prepare()` to prepare it, `mysql_stmt_bind_param()` to supply the parameter data, and `mysql_stmt_execute()` to execute the statement. You can repeat the `mysql_stmt_execute()` by changing parameter values in the respective buffers supplied through `mysql_stmt_bind_param()`.

If the statement is a `SELECT` or any other statement that produces a result set, `mysql_stmt_prepare()` also returns the result set metadata information in the form of a `MYSQL_RES` result set through `mysql_stmt_result_metadata()`.

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

You can also send the text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See [Section 28.2.7.25](#), “`mysql_stmt_send_long_data()`”.

When statement execution has been completed, the statement handle must be closed using `mysql_stmt_close()` so that all resources associated with it can be freed.

If you obtained a `SELECT` statement's result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

### Execution Steps

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handle with `mysql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.
2. If the statement produces a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of result set, albeit a separate one from the one that contains the rows returned by the query. The metadata result set indicates how many columns are in the result and contains information about each column.
3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.
4. Call `mysql_stmt_execute()` to execute the statement.
5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.
6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.
7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:

- The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.
- The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

- The client uses the statement handle and sends the parameter data to the server.
- The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set, the server sends the data back to the client. Otherwise, it sends an okay status and total number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

- The client reads the data from the packet row by row and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error code, error message, and SQLSTATE value using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, respectively.

### Prepared Statement Logging

For prepared statements that are executed with the `mysql_stmt_prepare()` and `mysql_stmt_execute()` C API functions, the server writes `Prepare` and `Execute` lines to the general query log so that you can tell when statements are prepared and executed.

Suppose that you prepare and execute a statement as follows:

1. Call `mysql_stmt_prepare()` to prepare the statement string `"SELECT ?"`.
2. Call `mysql_stmt_bind_param()` to bind the value `3` to the parameter in the prepared statement.
3. Call `mysql_stmt_execute()` to execute the prepared statement.

As a result of the preceding calls, the server writes the following lines to the general query log:

```
Prepare [1] SELECT ?
Execute [1] SELECT 3
```

Each `Prepare` and `Execute` line in the log is tagged with a `[N]` statement identifier so that you can keep track of which prepared statement is being logged. `N` is a positive integer. If there are multiple prepared statements active simultaneously for the client, `N` may be greater than 1. Each `Execute` line shows a prepared statement after substitution of data values for `?` parameters.

Version notes: `Prepare` lines are displayed without `[N]` before MySQL 4.1.10. `Execute` lines are not displayed at all before MySQL 4.1.10.

## 28.2.7. C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions described in detail in the following sections.

All functions that operate with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

To create a `MYSQL_STMT` handle, use the `mysql_stmt_init()` function.

### 28.2.7.1. `mysql_stmt_affected_rows()`

```
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```

#### Description

Returns the total number of rows changed, deleted, or inserted by the last executed statement. May be called immediately after `mysql_stmt_execute()` for `UPDATE`, `DELETE`, or `INSERT` statements. For `SELECT` statements, `mysql_stmt_affected_rows()` works like `mysql_num_rows()`.

#### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query, or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_stmt_affected_rows()` was called prior to calling `mysql_stmt_store_result()`. Because `mysql_stmt_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

See [Section 28.2.3.1](#), “`mysql_affected_rows()`”, for additional information on the return value.

#### Errors

None.

#### Example

For the usage of `mysql_stmt_affected_rows()`, refer to the Example from [Section 28.2.7.10](#), “`mysql_stmt_execute()`”.

### 28.2.7.2. `mysql_stmt_attr_get()`

```
my_bool mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, void *arg)
```

#### Description

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that should contain the option value. If the option is an integer, then `arg` should point to the value of the integer.

See [Section 28.2.7.3](#), “`mysql_stmt_attr_set()`”, for a list of options and option types.

#### Note

In MySQL 5.1, `mysql_stmt_attr_get()` originally used `unsigned int *`, not `my_bool *`, for `STMT_ATTR_UPDATE_MAX_LENGTH`. This was corrected in MySQL 5.1.7.

#### Return Values

Zero if successful. Non-zero if `option` is unknown.

#### Errors

None.

### 28.2.7.3. `mysql_stmt_attr_set()`

```
my_bool mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, const void *arg)
```

#### Description

Can be used to affect behavior for a prepared statement. This function may be called multiple times to set several options.

The `option` argument is the option that you want to set. The `arg` argument is the value for the option. `arg` should point to a variable that is set to the desired attribute value. The variable type is as indicated in the following table.

Possible `option` values:

| Option                                   | Argument Type                | Function                                                                                                                                                                                                  |
|------------------------------------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>STMT_ATTR_UPDATE_MAX_LENGTH</code> | <code>my_bool *</code>       | If set to 1: Update metadata <code>MYSQL_FIELD-&gt;max_length</code> in <code>mysql_stmt_store_result()</code> .                                                                                          |
| <code>STMT_ATTR_CURSOR_TYPE</code>       | <code>unsigned long *</code> | Type of cursor to open for statement when <code>mysql_stmt_execute()</code> is invoked. <code>*arg</code> can be <code>CURSOR_TYPE_NO_CURSOR</code> (the default) or <code>CURSOR_TYPE_READ_ONLY</code> . |
| <code>STMT_ATTR_PREFETCH_ROWS</code>     | <code>unsigned long *</code> | Number of rows to fetch from server at a time when using a cursor. <code>*arg</code> can be in the range from 1 to the maximum value of <code>unsigned long</code> . The default is 1.                    |

If you use the `STMT_ATTR_CURSOR_TYPE` option with `CURSOR_TYPE_READ_ONLY`, a cursor is opened for the statement when you invoke `mysql_stmt_execute()`. If there is already an open cursor from a previous `mysql_stmt_execute()` call, it closes the cursor before opening a new one. `mysql_stmt_reset()` also closes any open cursor before preparing the statement for re-execution. `mysql_stmt_free_result()` closes any open cursor.

If you open a cursor for a prepared statement, `mysql_stmt_store_result()` is unnecessary, because that function causes the result set to be buffered on the client side.

#### Return Values

Zero if successful. Non-zero if `option` is unknown.

**Errors**

None.

**Example**

The following example opens a cursor for a prepared statement and sets the number of rows to fetch at a time to 5:

```
MYSQL_STMT *stmt;
int rc;
unsigned long type;
unsigned long prefetch_rows = 5;

stmt = mysql_stmt_init(mysql);
type = (unsigned long) CURSOR_TYPE_READ_ONLY;
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_CURSOR_TYPE, (void*) &type);
/* ... check return value ... */
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_PREFETCH_ROWS,
 (void*) &prefetch_rows);
/* ... check return value ... */
```

**28.2.7.4. `mysql_stmt_bind_param()`**

```
my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

**Description**

`mysql_stmt_bind_param()` is used to bind input data for the parameter markers in the SQL statement that was passed to `mysql_stmt_prepare()`. It uses `MYSQL_BIND` structures to supply the data. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each “?” parameter marker that is present in the query.

Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?,?,?)
```

When you bind the parameters, the array of `MYSQL_BIND` structures must contain three elements, and can be declared like this:

```
MYSQL_BIND bind[3];
```

Section 28.2.5, “C API Prepared Statement Data types”, describes the members of each `MYSQL_BIND` element and how they should be set to provide input values.

**Return Values**

Zero if the bind operation was successful. Non-zero if an error occurred.

**Errors**

- `CR_UNSUPPORTED_PARAM_TYPE`

The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

**Example**

For the usage of `mysql_stmt_bind_param()`, refer to the Example from Section 28.2.7.10, “`mysql_stmt_execute()`”.

**28.2.7.5. `mysql_stmt_bind_result()`**

```
my_bool mysql_stmt_bind_result(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

**Description**

`mysql_stmt_bind_result()` is used to associate (that is, bind) output columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol doesn't return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol places data into the newly bound buffers when the next call to `mysql_stmt_fetch()` occurs.

To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and length of the output buffer into which the value should be stored. [Section 28.2.5, “C API Prepared Statement Data types”](#), describes the members of each `MYSQL_BIND` element and how they should be set to receive output values.

### Return Values

Zero if the bind operation was successful. Non-zero if an error occurred.

### Errors

- `CR_UNSUPPORTED_PARAM_TYPE`

The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### Example

For the usage of `mysql_stmt_bind_result()`, refer to the Example from [Section 28.2.7.11, “mysql\\_stmt\\_fetch\(\)”](#).

## 28.2.7.6. `mysql_stmt_close()`

```
my_bool mysql_stmt_close(MYSQL_STMT *)
```

### Description

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handle pointed to by `stmt`.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

### Return Values

Zero if the statement was freed successfully. Non-zero if an error occurred.

### Errors

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### Example

For the usage of `mysql_stmt_close()`, refer to the Example from [Section 28.2.7.10, “mysql\\_stmt\\_execute\(\)”](#).

### 28.2.7.7. `mysql_stmt_data_seek()`

```
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

#### Description

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from 0 to `mysql_stmt_num_rows(stmt)-1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

#### Return Values

None.

#### Errors

None.

### 28.2.7.8. `mysql_stmt_errno()`

```
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

#### Description

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix B, Errors, Error Codes, and Common Problems](#).

#### Return Values

An error code value. Zero if no error occurred.

#### Errors

None.

### 28.2.7.9. `mysql_stmt_error()`

```
const char *mysql_stmt_error(MYSQL_STMT *stmt)
```

#### Description

For the statement specified by `stmt`, `mysql_stmt_error()` returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string (" ") is returned if no error occurred. This means the following two tests are equivalent:

```
if (*mysql_stmt_errno(stmt))
{
 // an error occurred
}

if (mysql_stmt_error(stmt)[0])
{
 // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages.

#### Return Values

A character string that describes the error. An empty string if no error occurred.

#### Errors

None.

### 28.2.7.10. `mysql_stmt_execute()`

```
int mysql_stmt_execute(MYSQL_STMT *stmt)
```

### Description

`mysql_stmt_execute()` executes the prepared query associated with the statement handle. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

If the statement is an `UPDATE`, `DELETE`, or `INSERT`, the total number of changed, deleted, or inserted rows can be found by calling `mysql_stmt_affected_rows()`. If this is a statement such as `SELECT` that generates a result set, you must call `mysql_stmt_fetch()` to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to [Section 28.2.7.11](#), “`mysql_stmt_fetch()`”.

For statements that generate a result set, you can request that `mysql_stmt_execute()` open a cursor for the statement by calling `mysql_stmt_attr_set()` before executing the statement. If you execute a statement multiple times, `mysql_stmt_execute()` closes any open cursor before opening a new one.

As of MySQL 5.1.25, metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 12.7.1](#), “Automatic Prepared Statement Repreparation”.

### Return Values

Zero if execution was successful. Non-zero if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### Example

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(col1 INT,\
 col2 VARCHAR(40),\
 col3 SMALLINT,\
 col4 TIMESTAMP)"

#define INSERT_SAMPLE "INSERT INTO \
 test_table(col1,col2,col3) \
 VALUES(?,?,?)"

MYSQL_STMT *stmt;
MYSQL_BIND bind[3];
my_ulonglong affected_rows;
int param_count;
short small_data;
int int_data;
char str_data[STRING_SIZE];
unsigned long str_length;
my_bool is_null;

if (mysql_query(mysql, DROP_SAMPLE_TABLE))
{
```

```

fprintf(stderr, " DROP TABLE failed\n");
fprintf(stderr, " %s\n", mysql_error(mysql));
exit(0);
}

if (mysql_query(mysql, CREATE_SAMPLE_TABLE))
{
 fprintf(stderr, " CREATE TABLE failed\n");
 fprintf(stderr, " %s\n", mysql_error(mysql));
 exit(0);
}

/* Prepare an INSERT query with 3 parameters */
/* (the TIMESTAMP column is not named; the server */
/* sets it to the current date and time) */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
 fprintf(stderr, " mysql_stmt_init(), out of memory\n");
 exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_SAMPLE, strlen(INSERT_SAMPLE)))
{
 fprintf(stderr, " mysql_stmt_prepare(), INSERT failed\n");
 fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
 exit(0);
}
fprintf(stdout, " prepare, INSERT successful\n");

/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in INSERT: %d\n", param_count);

if (param_count != 3) /* validate parameter count */
{
 fprintf(stderr, " invalid parameter count returned by MySQL\n");
 exit(0);
}

/* Bind the data for all 3 parameters */
memset(bind, 0, sizeof(bind));

/* INTEGER PARAM */
/* This is a number type, so there is no need
to specify buffer_length */
bind[0].buffer_type= MYSQL_TYPE_LONG;
bind[0].buffer= (char *)&int_data;

 fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
 exit(0);
}

/* Get the total number of affected rows */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 1): %lu\n",
(unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
 fprintf(stderr, " invalid affected rows by MySQL\n");
 exit(0);
}

```

```

}
/* Specify data values for second row,
 then re-execute the statement */
int_data= 1000;
strncpy(str_data, "
 The most popular Open Source database",
 STRING_SIZE);
str_length= strlen(str_data);
small_data= 1000; /* smallint */
is_null= 0; /* reset */

/* Execute the INSERT statement - 2*/
if (mysql_stmt_execute(stmt))
{
 fprintf(stderr, " mysql_stmt_execute, 2 failed\n");
 fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
 exit(0);
}

/* Get the total rows affected */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 2): %lu\n",
 (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
 fprintf(stderr, " invalid affected rows by MySQL\n");
 exit(0);
}

/* Close the statement */
if (mysql_stmt_close(stmt))
{
 fprintf(stderr, " failed while closing the statement\n");
 fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
 exit(0);
}

```

**Note**

For complete examples on the use of prepared statement functions, refer to the file `tests/mysql_client_test.c`. This file can be obtained from a MySQL source distribution or from the Bazaar source repository.

**28.2.7.11. `mysql_stmt_fetch()`**

```
int mysql_stmt_fetch(MYSQL_STMT *stmt)
```

**Description**

`mysql_stmt_fetch()` returns the next row in the result set. It can be called only while the result set exists; that is, after a call to `mysql_stmt_execute()` for a statement such as `SELECT` that creates a result set.

`mysql_stmt_fetch()` returns row data using the buffers bound by `mysql_stmt_bind_result()`. It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the `length` pointer. All columns must be bound by the application before it calls `mysql_stmt_fetch()`.

By default, result sets are fetched unbuffered a row at a time from the server. To buffer the entire result set on the client, call `mysql_stmt_store_result()` after binding the data buffers and before calling `mysql_stmt_fetch()`.

If a fetched data value is a `NULL` value, the `*is_null` value of the corresponding `MYSQL_BIND` structure contains `TRUE` (1). Otherwise, the data and its length are returned in the `*buffer` and `*length` elements based on the buffer type specified by the application. Each numeric and temporal type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by `data_length`.

| Type                             | Length                          |
|----------------------------------|---------------------------------|
| <code>MYSQL_TYPE_TINY</code>     | 1                               |
| <code>MYSQL_TYPE_SHORT</code>    | 2                               |
| <code>MYSQL_TYPE_LONG</code>     | 4                               |
| <code>MYSQL_TYPE_LONGLONG</code> | 8                               |
| <code>MYSQL_TYPE_FLOAT</code>    | 4                               |
| <code>MYSQL_TYPE_DOUBLE</code>   | 8                               |
| <code>MYSQL_TYPE_TIME</code>     | <code>sizeof(MYSQL_TIME)</code> |
| <code>MYSQL_TYPE_DATE</code>     | <code>sizeof(MYSQL_TIME)</code> |
| <code>MYSQL_TYPE_DATETIME</code> | <code>sizeof(MYSQL_TIME)</code> |

|                                |                          |
|--------------------------------|--------------------------|
| <code>MYSQL_TYPE_STRING</code> | <code>data length</code> |
| <code>MYSQL_TYPE_BLOB</code>   | <code>data_length</code> |

### Return Values

| Return Value                      | Description                                                                                                                             |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 0                                 | Successful, the data has been fetched to application data buffers.                                                                      |
| 1                                 | Error occurred. Error code and message can be obtained by calling <code>mysql_stmt_errno()</code> and <code>mysql_stmt_error()</code> . |
| <code>MYSQL_NO_DATA</code>        | No more rows/data exists                                                                                                                |
| <code>MYSQL_DATA_TRUNCATED</code> | Data truncation occurred                                                                                                                |

`MYSQL_DATA_TRUNCATED` is returned when truncation reporting is enabled. (Reporting is enabled by default, but can be controlled with `mysql_options()`.) To determine which parameters were truncated when this value is returned, check the `error` members of the `MYSQL_BIND` parameter structures.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.
- `CR_UNSUPPORTED_PARAM_TYPE`  
The buffer type is `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, but the data type is not `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP`.
- All other unsupported conversion errors are returned from `mysql_stmt_bind_result()`.

### Example

The following example demonstrates how to fetch data from a table using `mysql_stmt_result_metadata()`, `mysql_stmt_bind_result()`, and `mysql_stmt_fetch()`. (This example expects to retrieve the two rows inserted by the example shown in Section 28.2.7.10, “`mysql_stmt_execute()`”). The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 \
 FROM test_table"

MYSQL_STMT *stmt;
MYSQL_BIND bind[4];
MYSQL_RES *prepare_meta_result;
MYSQL_TIME ts;
unsigned long length[4];
int param_count, column_count, row_count;
short small_data;
int int_data;
char str_data[STRING_SIZE];
my_bool is_null[4];
my_bool error[4];
```

```

/* Prepare a SELECT query to fetch data from test_table */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
 fprintf(stderr, " mysql_stmt_init(), out of memory\n");
 exit(0);
}
if (mysql_stmt_prepare(stmt, SELECT_SAMPLE, strlen(SELECT_SAMPLE)))
{
 fprintf(stderr, " mysql_stmt_prepare(), SELECT failed\n");
 fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
 exit(0);
}
fprintf(stdout, " prepare, SELECT successful\n");

/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in SELECT: %d\n", param_count);

if (param_count != 0) /* validate parameter count */
{
 fprintf(stderr, " invalid parameter count returned by MySQL\n");
 exit(0);
}

/* Fetch result set meta information */
prepare_meta_result = mysql_stmt_result_metadata(stmt);
if (!prepare_meta_result)
{

 else
 fprintf(stdout, " %04d-%02d-%02d %02d:%02d:%02d (%ld)\n",
 ts.year, ts.month, ts.day,
 ts.hour, ts.minute, ts.second,
 length[3]);
 fprintf(stdout, "\n");
}

/* Validate rows fetched */
fprintf(stdout, " total rows fetched: %d\n", row_count);
if (row_count != 2)
{
 fprintf(stderr, " MySQL failed to return all rows\n");
 exit(0);
}

/* Free the prepared result metadata */
mysql_free_result(prepare_meta_result);

/* Close the statement */
if (mysql_stmt_close(stmt))
{
 fprintf(stderr, " failed while closing the statement\n");
 fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
 exit(0);
}

```

In some cases you might want to determine the length of a column value before fetching it with `mysql_stmt_fetch()`. For example, the value might be a long string or `BLOB` value for which you want to know how much space must be allocated. To accomplish this, you can use these strategies:

- Before invoking `mysql_stmt_fetch()` to retrieve individual rows, invoke `mysql_stmt_store_result()` to buffer the entire result on the client side. Then the maximal length of column values will be indicated by the `max_length` member of the result set metadata returned by `mysql_stmt_result_metadata()`. This strategy requires that you pass `STMT_ATTR_UPDATE_MAX_LENGTH` to `mysql_stmt_attr_set()` or the `max_length` values will not be calculated.
- Invoke `mysql_stmt_fetch()` with a zero-length buffer for the column in question and a pointer in which the real length can be stored. Then use the real length with `mysql_stmt_fetch_column()`.

```

real_length= 0;

bind[0].buffer= 0;
bind[0].buffer_length= 0;
bind[0].length= &real_length;
mysql_stmt_bind_result(stmt, bind);

mysql_stmt_fetch(stmt);
if (real_length > 0)

```

```
{
 data= malloc(real_length);
 bind[0].buffer= data;
 bind[0].buffer_length= real_length;
 mysql_stmt_fetch_column(stmt, 0, bind, 0);
}
```

### 28.2.7.12. `mysql_stmt_fetch_column()`

```
int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, unsigned int column, unsigned long offset)
```

#### Description

Fetch one column from the current result set row. `bind` provides the buffer where data should be placed. It should be set up the same way as for `mysql_stmt_bind_result()`. `column` indicates which column to fetch. The first column is numbered 0. `offset` is the offset within the data value at which to begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is offset 0.

As of MySQL 5.1.25, metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 12.7.1, “Automatic Prepared Statement Reparation”](#).

#### Return Values

Zero if the value was fetched successfully. Non-zero if an error occurred.

#### Errors

- `CR_INVALID_PARAMETER_NO`  
Invalid column number.
- `CR_NO_DATA`  
The end of the result set has already been reached.

### 28.2.7.13. `mysql_stmt_field_count()`

```
unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)
```

#### Description

Returns the number of columns for the most recent statement for the statement handler. This value is zero for statements such as `INSERT` or `DELETE` that do not produce result sets.

`mysql_stmt_field_count()` can be called after you have prepared a statement by invoking `mysql_stmt_prepare()`.

#### Return Values

An unsigned integer representing the number of columns in a result set.

#### Errors

None.

### 28.2.7.14. `mysql_stmt_free_result()`

```
my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)
```

#### Description

Releases memory associated with the result set produced by execution of the prepared statement. If there is a cursor open for the statement, `mysql_stmt_free_result()` closes it.

#### Return Values

Zero if the result set was freed successfully. Non-zero if an error occurred.

**Errors****28.2.7.15. `mysql_stmt_init()`**

```
MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)
```

**Description**

Create a `MYSQL_STMT` handle. The handle should be freed with `mysql_stmt_close(MYSQL_STMT *)`.

**Return values**

A pointer to a `MYSQL_STMT` structure in case of success. `NULL` if out of memory.

**Errors**

- `CR_OUT_OF_MEMORY`  
Out of memory.

**28.2.7.16. `mysql_stmt_insert_id()`**

```
my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)
```

**Description**

Returns the value generated for an `AUTO_INCREMENT` column by the prepared `INSERT` or `UPDATE` statement. Use this function after you have executed a prepared `INSERT` statement on a table which contains an `AUTO_INCREMENT` field.

See [Section 28.2.3.37](#), “`mysql_insert_id()`”, for more information.

**Return Values**

Value for `AUTO_INCREMENT` column which was automatically generated or explicitly set during execution of prepared statement, or value generated by `LAST_INSERT_ID(expr)` function. Return value is undefined if statement does not set `AUTO_INCREMENT` value.

**Errors**

None.

**28.2.7.17. `mysql_stmt_num_rows()`**

```
my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)
```

**Description**

Returns the number of rows in the result set.

The use of `mysql_stmt_num_rows()` depends on whether you used `mysql_stmt_store_result()` to buffer the entire result set in the statement handle.

If you use `mysql_stmt_store_result()`, `mysql_stmt_num_rows()` may be called immediately. Otherwise, the row count is unavailable unless you count the rows as you fetch them.

`mysql_stmt_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_stmt_affected_rows()`.

**Return Values**

The number of rows in the result set.

**Errors**

None.

**28.2.7.18. `mysql_stmt_param_count()`**

```
unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)
```

---

**Description**

Returns the number of parameter markers present in the prepared statement.

**Return Values**

An unsigned long integer representing the number of parameters in a statement.

**Errors**

None.

**Example**

For the usage of `mysql_stmt_param_count()`, refer to the Example from [Section 28.2.7.10](#), `"mysql_stmt_execute()"`.

**28.2.7.19. `mysql_stmt_param_metadata()`**

```
MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)
```

This function currently does nothing.

**Description****Return Values****Errors****28.2.7.20. `mysql_stmt_prepare()`**

```
int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *stmt_str, unsigned long length)
```

**Description**

Given the statement handle returned by `mysql_stmt_init()`, prepares the SQL statement pointed to by the string `stmt_str` and returns a status value. The string length should be given by the `length` argument. The string must consist of a single SQL statement. You should not add a terminating semicolon ("`;`") or `\g` to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark ("`?`") characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are allowed in the `VALUES()` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value. However, they are not allowed for identifiers (such as table or column names), or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using `mysql_stmt_bind_param()` before executing the statement.

**Return Values**

Zero if the statement was prepared successfully. Non-zero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

If the prepare operation was unsuccessful (that is, `mysql_stmt_prepare()` returns non-zero), the error message can be obtained by calling `mysql_stmt_error()`.

#### Example

For the usage of `mysql_stmt_prepare()`, refer to the Example from [Section 28.2.7.10](#), “`mysql_stmt_execute()`”.

### 28.2.7.21. `mysql_stmt_reset()`

```
my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
```

#### Description

Reset the prepared statement on the client and server to state after prepare. This is mainly used to reset data sent with `mysql_stmt_send_long_data()`. Any open cursor for the statement is closed.

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

#### Return Values

Zero if the statement was reset successfully. Non-zero if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 28.2.7.22. `mysql_stmt_result_metadata()`

```
MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)
```

#### Description

If a statement passed to `mysql_stmt_prepare()` is one that produces a result set, `mysql_stmt_result_metadata()` returns the result set metadata in the form of a pointer to a `MYSQL_RES` structure that can be used to process the meta information such as total number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- `mysql_num_fields()`
- `mysql_fetch_field()`
- `mysql_fetch_field_direct()`
- `mysql_fetch_fields()`

- `mysql_field_count()`
- `mysql_field_seek()`
- `mysql_field_tell()`
- `mysql_free_result()`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysql_free_result()`. This is similar to the way you free a result set obtained from a call to `mysql_store_result()`.

The result set returned by `mysql_stmt_result_metadata()` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysql_stmt_fetch()`.

### Return Values

A `MYSQL_RES` result structure. `NULL` if no meta information exists for the prepared query.

### Errors

- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### Example

For the usage of `mysql_stmt_result_metadata()`, refer to the Example from [Section 28.2.7.11](#), “`mysql_stmt_fetch()`”.

## 28.2.7.23. `mysql_stmt_row_seek()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_seek(MYSQL_STMT *stmt, MYSQL_ROW_OFFSET offset)
```

### Description

Sets the row cursor to an arbitrary row in a statement result set. The `offset` value is a row offset that should be a value returned from `mysql_stmt_row_tell()` or from `mysql_stmt_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_stmt_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_stmt_row_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

### Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_stmt_row_seek()`.

### Errors

None.

## 28.2.7.24. `mysql_stmt_row_tell()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)
```

### Description

Returns the current position of the row cursor for the last `mysql_stmt_fetch()`. This value can be used as an argument to `mysql_stmt_row_seek()`.

You should use `mysql_stmt_row_tell()` only after `mysql_stmt_store_result()`.

### Return Values

The current offset of the row cursor.

**Errors**

None.

**28.2.7.25. `mysql_stmt_send_long_data()`**

```
my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int parameter_number, const
char *data, unsigned long length)
```

**Description**

Allows an application to send parameter data to the server in pieces (or “chunks”). Call this function after `mysql_stmt_bind_param()` and before `mysql_stmt_execute()`. It can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the `TEXT` or `BLOB` data types.

`parameter_number` indicates which parameter to associate the data with. Parameters are numbered beginning with 0. `data` is a pointer to a buffer containing data to be sent, and `length` indicates the number of bytes in the buffer.

**Note**

The next `mysql_stmt_execute()` call ignores the bind buffer for all parameters that have been used with `mysql_stmt_send_long_data()` since last `mysql_stmt_execute()` or `mysql_stmt_reset()`.

If you want to reset/forget the sent data, you can do it with `mysql_stmt_reset()`. See [Section 28.2.7.21](#), “`mysql_stmt_reset()`”.

**Return Values**

Zero if the data is sent successfully to server. Non-zero if an error occurred.

**Errors**

- `CR_INVALID_BUFFER_USE`  
The parameter does not have a string or binary type.
- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

**Example**

The following example demonstrates how to send the data for a `TEXT` column in chunks. It inserts the data value `'MySQL - The most popular Open Source database'` into the `text_column` column. The `mysql` variable is assumed to be a valid connection handle.

```
#define INSERT_QUERY "INSERT INTO \
 test_long_data(text_column) VALUES(?)"

MYSQL_BIND bind[1];
long length;

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
 fprintf(stderr, "mysql_stmt_init(), out of memory\n");
 exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY)))
{
 fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
 fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
}
```

```

 exit(0);
}
memset(bind, 0, sizeof(bind));
bind[0].buffer_type= MYSQL_TYPE_STRING;
bind[0].length= &length;
bind[0].is_null= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
 fprintf(stderr, "\n param bind failed");
 fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
 exit(0);
}

/* Supply data in chunks to server */
if (mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
 fprintf(stderr, "\n send_long_data failed");
 fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
 exit(0);
}

/* Supply the next piece of data */
if (mysql_stmt_send_long_data(stmt,0,
 " - The most popular Open Source database",40))
{
 fprintf(stderr, "\n send_long_data failed");
 fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
 exit(0);
}

/* Now, execute the query */
if (mysql_stmt_execute(stmt))
{
 fprintf(stderr, "\n mysql_stmt_execute failed");
 fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
 exit(0);
}

```

### 28.2.7.26. `mysql_stmt_sqlstate()`

```
const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)
```

#### Description

For the statement specified by `stmt`, `mysql_stmt_sqlstate()` returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. "00000" means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix B, Errors, Error Codes, and Common Problems](#).

Note that not all MySQL errors are yet mapped to SQLSTATE codes. The value "HY000" (general error) is used for unmapped errors.

#### Return Values

A null-terminated character string containing the SQLSTATE error code.

### 28.2.7.27. `mysql_stmt_store_result()`

```
int mysql_stmt_store_result(MYSQL_STMT *stmt)
```

#### Description

Result sets are produced by executing prepared statements for SQL statements such as `SELECT`, `SHOW`, `DESCRIBE`, and `EXPLAIN`. By default, result sets for successfully executed prepared statements are not buffered on the client and `mysql_stmt_fetch()` fetches them one at a time from the server. To cause the complete result set to be buffered on the client, call `mysql_stmt_store_result()` after binding data buffers with `mysql_stmt_bind_result()` and before calling `mysql_stmt_fetch()` to fetch rows. (For an example, see [Section 28.2.7.11](#), "mysql\_stmt\_fetch().")

`mysql_stmt_store_result()` is optional for result set processing, unless you will call `mysql_stmt_data_seek()`, `mysql_stmt_row_seek()`, or `mysql_stmt_row_tell()`. Those functions require a seekable result set.

It is unnecessary to call `mysql_stmt_store_result()` after executing a SQL statement that does not produce a result set, but if you do, it does not harm or cause any notable performance problem. You can detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns `NULL`. For more information, refer to [Section 28.2.7.22](#), "mysql\_stmt\_result\_metadata()."

#### Note

MySQL doesn't by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications doesn't need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STMT_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See [Section 28.2.7.3](#), “`mysql_stmt_attr_set()`”.

### Return Values

Zero if the results are buffered successfully. Non-zero if an error occurred.

### Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)  
Commands were executed in an improper order.
- [CR\\_OUT\\_OF\\_MEMORY](#)  
Out of memory.
- [CR\\_SERVER\\_GONE\\_ERROR](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST](#)  
The connection to the server was lost during the query.
- [CR\\_UNKNOWN\\_ERROR](#)  
An unknown error occurred.

## 28.2.8. C API Prepared Statement Problems

Here follows a list of the currently known problems with prepared statements:

- [TIME](#), [TIMESTAMP](#), and [DATETIME](#) do not support parts of seconds (for example, from `DATE_FORMAT()`).
- When converting an integer to string, [ZEROFILL](#) is honored with prepared statements in some cases where the MySQL server doesn't print the leading zeros. (For example, with `MIN(number-with-zerofill)`).
- When converting a floating-point number to a string in the client, the rightmost digits of the converted value may differ slightly from those of the original value.
- Before MySQL 5.1.17, prepared statements do not use the query cache. As of 5.1.17, prepared statements use the query cache under the conditions described in [Section 7.5.4.1](#), “[How the Query Cache Operates](#)”.
- Prepared statements do not support multi-statements (that is, multiple statements within a single string separated by “;” characters). This also means that prepared statements cannot invoke stored procedures that return result sets, because prepared statements do not support multiple result sets.

## 28.2.9. C API Handling of Multiple Statement Execution

By default, `mysql_query()` and `mysql_real_query()` interpret their statement string argument as a single statement to be executed, and you process the result according to whether the statement produces a result set (a set of rows, as for [SELECT](#)) or an affected-rows count (as for [INSERT](#), [UPDATE](#), and so forth).

MySQL 5.1 also supports the execution of a string containing multiple statements separated by semicolon (“;”) characters. This capability is enabled by special options that are specified either when you connect to the server with `mysql_real_connect()` or after connecting by calling `mysql_set_server_option()`.

Executing a multiple-statement string can produce multiple result sets or row-count indicators. Processing these results involves a different approach than for the single-statement case: After handling the result from the first statement, it is necessary to check whether more results exist and process them in turn if so. To support multiple-result processing, the C API includes the `mysql_more_results()` and `mysql_next_result()` functions. These functions are used at the end of a loop that iterates as long as more results are available. *Failure to process the result this way may result in a dropped connection to the server.*

Multiple-result processing also is required if you execute `CALL` statements for stored procedures. Results from a stored procedure have these characteristics:

- Statements within the procedure may produce result sets (for example, if it executes `SELECT` statements). These result sets are returned in the order that they are produced as the procedure executes.

In general, the caller cannot know how many result sets a procedure will return. Procedure execution may depend on loops or conditional statements that cause the execution path to differ from one call to the next. Therefore, you must be prepared to retrieve multiple results.

- The final result from the procedure is a status result that includes no result set. The status indicates whether the procedure succeeded or an error occurred.

The multiple statement and result capabilities can be used only with `mysql_query()` or `mysql_real_query()`. They cannot be used with the prepared statement interface. Prepared statement handles are defined to work only with strings that contain a single statement. See [Section 28.2.4, “C API Prepared Statements”](#).

To enable multiple-statement execution and result processing, the following options may be used:

- The `mysql_real_connect()` function has a `flags` argument for which two option values are relevant:
  - `CLIENT_MULTI_RESULTS` enables the client program to process multiple results. This option *must* be enabled if you execute `CALL` statements for stored procedures that produce result sets. Otherwise, such procedures result in an error `Error 1312 (0A000): PROCEDURE proc_name can't return a result set in the given context`.
  - `CLIENT_MULTI_STATEMENTS` enables `mysql_query()` and `mysql_real_query()` to execute statement strings containing multiple statements separated by semicolons. This option also enables `CLIENT_MULTI_RESULTS` implicitly, so a `flags` argument of `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()` is equivalent to an argument of `CLIENT_MULTI_STATEMENTS | CLIENT_MULTI_RESULTS`. That is, `CLIENT_MULTI_STATEMENTS` is sufficient to enable multiple-statement execution and all multiple-result processing.
- After the connection to the server has been established, you can use the `mysql_set_server_option()` function to enable or disable multiple-statement execution by passing it an argument of `MYSQL_OPTION_MULTI_STATEMENTS_ON` or `MYSQL_OPTION_MULTI_STATEMENTS_OFF`. Enabling multiple-statement execution with this function also enables processing of “simple” results for a multiple-statement string where each statement produces a single result, but is *not* sufficient to allow processing of stored procedures that produce result sets.

The following procedure outlines a suggested strategy for handling multiple statements:

1. Pass `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()`, to fully enable multiple-statement execution and multiple-result processing.
2. After calling `mysql_query()` or `mysql_real_query()` and verifying that it succeeds, enter a loop within which you process statement results.
3. For each iteration of the loop, handle the current statement result, retrieving either a result set or an affected-rows count. If an error occurs, exit the loop.
4. At the end of the loop, call `mysql_next_result()` to check whether another result exists and initiate retrieval for it if so. If no more results are available, exit the loop.

One possible implementation of the preceding strategy is shown following. The final part of the loop can be reduced to a simple test of whether `mysql_next_result()` returns non-zero. The code as written distinguishes between no more results and an error, which allows a message to be printed for the latter occurrence.

```
/* connect to server with the CLIENT_MULTI_STATEMENTS option */
if (mysql_real_connect (mysql, host_name, user_name, password,
 db_name, port_num, socket_name, CLIENT_MULTI_STATEMENTS) == NULL)
{
 printf("mysql_real_connect() failed\n");
 mysql_close(mysql);
 exit(1);
}

/* execute multiple statements */
status = mysql_query(mysql,
 "DROP TABLE IF EXISTS test_table;\n
 CREATE TABLE test_table(id INT);\n
 INSERT INTO test_table VALUES(10);\n
```

```

UPDATE test_table SET id=20 WHERE id=10;\
SELECT * FROM test_table;\
DROP TABLE test_table");
if (status)
{
 printf("Could not execute statement(s)");
 mysql_close(mysql);
 exit(0);
}

/* process each statement result */
do {
 /* did current statement return data? */
 result = mysql_store_result(mysql);
 if (result)
 {
 /* yes; process rows and free the result set */
 process_result_set(mysql, result);
 mysql_free_result(result);
 }
 else /* no result set or error */
 {
 if (mysql_field_count(mysql) == 0)
 {
 printf("%lld rows affected\n",
 mysql_affected_rows(mysql));
 }
 else /* some error occurred */
 {
 printf("Could not retrieve result set\n");
 break;
 }
 }
 /* more results? -1 = no, >0 = error, 0 = yes (keep looping) */
 if ((status = mysql_next_result(mysql)) > 0)
 printf("Could not execute statement\n");
} while (status == 0);

mysql_close(mysql);

```

## 28.2.10. C API Handling of Date and Time Values

The binary (prepared statement) protocol allows you to send and receive date and time values ([DATE](#), [TIME](#), [DATETIME](#), and [TIMESTAMP](#)), using the [MYSQL\\_TIME](#) structure. The members of this structure are described in [Section 28.2.5, “C API Prepared Statement Data Types”](#).

To send temporal data values, create a prepared statement using [mysql\\_stmt\\_prepare\(\)](#). Then, before calling [mysql\\_stmt\\_execute\(\)](#) to execute the statement, use the following procedure to set up each temporal parameter:

1. In the [MYSQL\\_BIND](#) structure associated with the data value, set the [buffer\\_type](#) member to the type that indicates what kind of temporal value you're sending. For [DATE](#), [TIME](#), [DATETIME](#), or [TIMESTAMP](#) values, set [buffer\\_type](#) to [MYSQL\\_TYPE\\_DATE](#), [MYSQL\\_TYPE\\_TIME](#), [MYSQL\\_TYPE\\_DATETIME](#), or [MYSQL\\_TYPE\\_TIMESTAMP](#), respectively.
2. Set the [buffer](#) member of the [MYSQL\\_BIND](#) structure to the address of the [MYSQL\\_TIME](#) structure in which you pass the temporal value.
3. Fill in the members of the [MYSQL\\_TIME](#) structure that are appropriate for the type of temporal value to be passed.

Use [mysql\\_stmt\\_bind\\_param\(\)](#) to bind the parameter data to the statement. Then you can call [mysql\\_stmt\\_execute\(\)](#).

To retrieve temporal values, the procedure is similar, except that you set the [buffer\\_type](#) member to the type of value you expect to receive, and the [buffer](#) member to the address of a [MYSQL\\_TIME](#) structure into which the returned value should be placed. Use [mysql\\_stmt\\_bind\\_result\(\)](#) to bind the buffers to the statement after calling [mysql\\_stmt\\_execute\(\)](#) and before fetching the results.

Here is a simple example that inserts [DATE](#), [TIME](#), and [TIMESTAMP](#) data. The [mysql](#) variable is assumed to be a valid connection handle.

```

MYSQL_TIME ts;
MYSQL_BIND bind[3];
MYSQL_STMT *stmt;

strmov(query, "INSERT INTO test_table(date_field, time_field, \
 timestamp_field) VALUES(?,?,?)");

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
 fprintf(stderr, " mysql_stmt_init(), out of memory\n");
 exit(0);
}

```

```

}
if (mysql_stmt_prepare(mysql, query, strlen(query)))
{
 fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
 fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
 exit(0);
}

/* set up input buffers for all 3 parameters */
bind[0].buffer_type= MYSQL_TYPE_DATE;
bind[0].buffer= (char *)&ts;
bind[0].is_null= 0;
bind[0].length= 0;
...
bind[1]= bind[2]= bind[0];
...

mysql_stmt_bind_param(stmt, bind);

/* supply the data to be sent in the ts structure */
ts.year= 2002;
ts.month= 02;
ts.day= 03;

ts.hour= 10;
ts.minute= 45;
ts.second= 20;

mysql_stmt_execute(stmt);
..

```

## 28.2.11. C API Threaded Function Descriptions

You need to use the following functions when you want to create a threaded client. See [Section 28.2.16, “How to Make a Threaded Client”](#).

### 28.2.11.1. `my_init()`

```
void my_init(void)
```

#### Description

`my_init()` initializes some global variables that MySQL needs. If you are using a thread-safe client library, it also calls `mysql_thread_init()` for this thread.

It is necessary for `my_init()` to be called early in the initialization phase of a program's use of the MySQL library. However, `my_init()` is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you ensure that your program invokes one of those functions before any other MySQL calls, there is no need to invoke `my_init()` explicitly.

To access `my_init()`, your program must include the `my_sys.h` header file:

```
#include <my_sys.h>
```

#### Return Values

None.

### 28.2.11.2. `mysql_thread_end()`

```
void mysql_thread_end(void)
```

#### Description

This function needs to be called before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

`mysql_thread_end()` is not invoked automatically by the client library. It must be called explicitly to avoid a memory leak.

#### Return Values

None.

### 28.2.11.3. `mysql_thread_init()`

```
my_bool mysql_thread_init(void)
```

**Description**

This function must be called early within each created thread to initialize thread-specific variables. However, you may not necessarily need to invoke it explicitly: `mysql_thread_init()` is automatically called by `my_init()`, which itself is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you invoke any of those functions, `mysql_thread_init()` will be called for you.

**Return Values**

Zero if successful. Non-zero if an error occurred.

**28.2.11.4. `mysql_thread_safe()`**

```
unsigned int mysql_thread_safe(void)
```

**Description**

This function indicates whether the client library is compiled as thread-safe.

**Return Values**

1 if the client library is thread-safe, 0 otherwise.

**28.2.12. C API Embedded Server Function Descriptions**

MySQL applications can be written to use an embedded server. See [Section 28.1, “libmysqld, the Embedded MySQL Server Library”](#). To write such an application, you must link it against the `libmysqld` library by using the `-lmysqld` flag rather than linking it against the `libmysqlclient` client library by using the `-libmysqlclient` flag. However, the calls to initialize and finalize the library are the same whether you write a client application or one that uses the embedded server: Call `mysql_library_init()` to initialize the library and `mysql_library_end()` when you are done with it. See [Section 28.2.2, “C API Function Overview”](#).

**28.2.12.1. `mysql_server_init()`**

```
int mysql_server_init(int argc, char **argv, char **groups)
```

**Description**

This function initializes the MySQL library, which must be done before you call any other MySQL function. However, `mysql_server_init()` is deprecated and you should call `mysql_library_init()` instead. See [Section 28.2.3.40, “mysql\\_library\\_init\(\)”](#).

**Return Values**

Zero if successful. Non-zero if an error occurred.

**28.2.12.2. `mysql_server_end()`**

```
void mysql_server_end(void)
```

**Description**

This function finalizes the MySQL library, which should be done when you are done using the library. However, `mysql_server_end()` is deprecated and `mysql_library_end()` should be used instead. See [Section 28.2.3.39, “mysql\\_library\\_end\(\)”](#).

**Return Values**

None.

**28.2.13. Controlling Automatic Reconnect Behavior**

The MySQL client library can perform an automatic reconnect to the server if it finds that the connection is down when you attempt to send a statement to the server to be executed. In this case, the library tries once to reconnect to the server and send the statement again.

If it is important for your application to know that the connection has been dropped (so that it can exit or take action to adjust for the loss of state information), be sure to disable auto-reconnect. This can be done explicitly by calling `mysql_options()` with the `MYSQL_OPT_RECONNECT` option:

```
my_bool reconnect = 0;
mysql_options(&mysql, MYSQL_OPT_RECONNECT, &reconnect);
```

In MySQL 5.1, auto-reconnect is disabled by default.

Some client programs might provide the capability of controlling automatic reconnection. For example, `mysql` reconnects by default, but the `--skip-reconnect` option can be used to suppress this behavior.

Automatic reconnection can be convenient because you need not implement your own reconnect code, but if a reconnection does occur, several aspects of the connection state are reset and your application will not know about it. The connection-related state is affected as follows:

- Any active transactions are rolled back and autocommit mode is reset.
- All table locks are released.
- All `TEMPORARY` tables are closed (and dropped).
- Session variables are reinitialized to the values of the corresponding variables. This also affects variables that are set implicitly by statements such as `SET NAMES`.
- User variable settings are lost.
- Prepared statements are released.
- `HANDLER` variables are closed.
- The value of `LAST_INSERT_ID()` is reset to 0.
- Locks acquired with `GET_LOCK()` are released.
- `mysql_ping()` does not attempt a reconnection if the connection is down. It returns an error instead.

## 28.2.14. Common Questions and Problems When Using the C API

### MySQL Enterprise

Subscribers to MySQL Enterprise will find articles about the C API in the MySQL Knowledge Base. Access to the Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

### 28.2.14.1. Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success

It is possible for `mysql_store_result()` to return `NULL` following a successful call to `mysql_query()`. When this happens, it means one of the following conditions occurred:

- There was a `malloc()` failure (for example, if the result set was too large).
- The data couldn't be read (an error occurred on the connection).
- The query returned no data (for example, it was an `INSERT`, `UPDATE`, or `DELETE`).

You can always check whether the statement should have produced a non-empty result by calling `mysql_field_count()`. If `mysql_field_count()` returns zero, the result is empty and the last query was a statement that does not return values (for example, an `INSERT` or a `DELETE`). If `mysql_field_count()` returns a non-zero value, the statement should have produced a non-empty result. See the description of the `mysql_field_count()` function for an example.

You can test for an error by calling `mysql_error()` or `mysql_errno()`.

### 28.2.14.2. What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- `mysql_affected_rows()` returns the number of rows affected by the last query when doing an `INSERT`, `UPDATE`, or `DELETE`.

For a fast re-create, use `TRUNCATE TABLE`.

- `mysql_num_rows()` returns the number of rows in a result set. With `mysql_store_result()`, `mysql_num_rows()` may be called as soon as `mysql_store_result()` returns. With `mysql_use_result()`, `mysql_num_rows()` may be called only after you have fetched all the rows with `mysql_fetch_row()`.
- `mysql_insert_id()` returns the ID generated by the last query that inserted a row into a table with an `AUTO_INCREMENT` index. See [Section 28.2.3.37](#), “`mysql_insert_id()`”.
- Some queries (`LOAD DATA INFILE ...`, `INSERT INTO ... SELECT ...`, `UPDATE`) return additional information. The result is returned by `mysql_info()`. See the description for `mysql_info()` for the format of the string that it returns. `mysql_info()` returns a `NULL` pointer if there is no additional information.

### 28.2.14.3. How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an `AUTO_INCREMENT` column, you can obtain the value stored into that column by calling the `mysql_insert_id()` function.

You can check from your C applications whether a value was stored in an `AUTO_INCREMENT` column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an `INSERT` with an `AUTO_INCREMENT` index:

```
if ((result = mysql_store_result(&mysql)) == 0 &&
 mysql_field_count(&mysql) == 0 &&
 mysql_insert_id(&mysql) != 0)
{
 used_id = mysql_insert_id(&mysql);
}
```

When a new `AUTO_INCREMENT` value has been generated, you can also obtain it by executing a `SELECT LAST_INSERT_ID()` statement with `mysql_query()` and retrieving the value from the result set returned by the statement.

When inserting multiple values, the last automatically incremented value is returned.

For `LAST_INSERT_ID()`, the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another `AUTO_INCREMENT` column with a non-magic value (that is, a value that is not `NULL` and not `0`). Using `LAST_INSERT_ID()` and `AUTO_INCREMENT` columns simultaneously from multiple clients is perfectly valid. Each client will receive the last inserted ID for the last statement *that* client executed.

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```
INSERT INTO foo (auto,text)
VALUES(NULL,'text'); # generate ID by inserting NULL
INSERT INTO foo2 (id,text)
VALUES(LAST_INSERT_ID(),'text'); # use ID in second table
```

Note that `mysql_insert_id()` returns the value stored into an `AUTO_INCREMENT` column, whether that value is automatically generated by storing `NULL` or `0` or was specified as an explicit value. `LAST_INSERT_ID()` returns only automatically generated `AUTO_INCREMENT` values. If you store an explicit value other than `NULL` or `0`, it does not affect the value returned by `LAST_INSERT_ID()`.

For more information on obtaining the last ID in an `AUTO_INCREMENT` column:

- For information on `LAST_INSERT_ID()`, which can be used within an SQL statement, see [Section 11.11.3](#), “Information Functions”.
- For information on `mysql_insert_id()`, the function you use from within the C API, see [Section 28.2.3.37](#), “`mysql_insert_id()`”.
- For information on obtaining the auto-incremented value when using Connector/J, see [Section 29.4.5](#), “Connector/J Notes and Tips”.
- For information on obtaining the auto-incremented value when using Connector/ODBC, see [Section 29.1.7.1.1](#), “Obtaining Auto-Increment Values”.

### 28.2.14.4. Problems Linking with the C API

When linking with the C API, the following errors may occur on some systems:

```
gcc -g -o client test.o -L/usr/local/lib/mysql \
 -lmysqlclient -lsocket -lnsl

Undefined first referenced
symbol in file
floor /usr/local/lib/mysql/libmysqlclient.a(password.o)
ld: fatal: Symbol referencing errors. No output written to client
```

If this happens on your system, you must include the math library by adding `-lm` to the end of the compile/link line.

## 28.2.15. Building Client Programs

If you compile MySQL clients that you've written yourself or that you obtain from a third-party, they must be linked using the `-lmysqlclient -lz` options in the link command. You may also need to specify a `-L` option to tell the linker where to find the library. For example, if the library is installed in `/usr/local/mysql/lib`, use `-L/usr/local/mysql/lib -lmysqlclient -lz` in the link command.

For clients that use MySQL header files, you may need to specify an `-I` option when you compile them (for example, `-I/usr/local/mysql/include`), so that the compiler can find the header files.

To make it simpler to compile MySQL programs on Unix, we have provided the `mysql_config` script for you. See [Section 4.7.2, “mysql\\_config — Get Compile Options for Compiling Clients”](#).

You can use it to compile a MySQL client as follows:

```
CFG=/usr/local/mysql/bin/mysql_config
sh -c "gcc -o progname ` $CFG --cflags ` progname.c ` $CFG --libs `"
```

The `sh -c` is needed to get the shell not to treat the output from `mysql_config` as one word.

### MySQL Enterprise

Subscribers to MySQL Enterprise will find an example client program in the Knowledge Base article, [Sample C program using the embedded MySQL server library](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

## 28.2.16. How to Make a Threaded Client

The client library is almost thread-safe. The biggest problem is that the subroutines in `net.c` that read from sockets are not interrupt safe. This was done with the thought that you might want to have your own alarm that can break a long read to a server. If you install interrupt handlers for the `SIGPIPE` interrupt, the socket handling should be thread-safe.

To avoid aborting the program when a connection terminates, MySQL blocks `SIGPIPE` on the first call to `mysql_library_init()`, `mysql_init()`, or `mysql_connect()`. If you want to use your own `SIGPIPE` handler, you should first call `mysql_library_init()` and then install your handler.

Before MySQL 4.0, binary client libraries that we provided other than those for Windows were not normally compiled with the thread-safe option. Current binary distributions should have both a normal and a thread-safe client library.

To create a threaded client where you can interrupt the client from other threads and set timeouts when talking with the MySQL server, you should use the `net_serv.o` code that the server uses and the `-lmysys`, `-lmystings`, and `-ldbbug` libraries.

If you don't need interrupts or timeouts, you can just compile a thread-safe client library (`mysqlclient_r`) and use it. In this case, you don't have to worry about the `net_serv.o` object file or the other MySQL libraries.

When using a threaded client and you want to use timeouts and interrupts, you can make great use of the routines in the `thr_alarm.c` file. If you are using routines from the `mysys` library, the only thing you must remember is to call `my_init()` first! See [Section 28.2.11, “C API Threaded Function Descriptions”](#).

In all cases, be sure to initialize the client library by calling `mysql_library_init()` before calling any other MySQL functions. When you are done with the library, call `mysql_library_end()`.

`mysql_real_connect()` is not thread-safe by default. The following notes describe how to compile a thread-safe client library and use it in a thread-safe manner. (The notes below for `mysql_real_connect()` also apply to the older `mysql_connect()` routine as well, although `mysql_connect()` is deprecated and should no longer be used.)

To make `mysql_real_connect()` thread-safe, you must configure your MySQL distribution with this command:

```
shell> ./configure --enable-thread-safe-client
```

Then recompile the distribution to create a thread-safe client library, `libmysqlclient_r`. (Assuming that your operating system has a thread-safe `gethostbyname_r()` function.) This library is thread-safe per connection. You can let two threads share the same connection with the following caveats:

- Two threads can't send a query to the MySQL server at the same time on the same connection. In particular, you have to ensure that between calls to `mysql_query()` and `mysql_store_result()` no other thread is using the same connection.
- Many threads can access different result sets that are retrieved with `mysql_store_result()`.
- If you use `mysql_use_result()`, you must ensure that no other thread is using the same connection until the result set is closed. However, it really is best for threaded clients that share the same connection to use `mysql_store_result()`.
- If you want to use multiple threads on the same connection, you must have a mutex lock around your pair of `mysql_query()` and `mysql_store_result()` calls. Once `mysql_store_result()` is ready, the lock can be released and other threads may query the same connection.
- If you use POSIX threads, you can use `pthread_mutex_lock()` and `pthread_mutex_unlock()` to establish and release a mutex lock.

You need to know the following if you have a thread that is calling MySQL functions which did not create the connection to the MySQL database:

When you call `mysql_init()`, MySQL creates a thread-specific variable for the thread that is used by the debug library (among other things). If you call a MySQL function before the thread has called `mysql_init()`, the thread does not have the necessary thread-specific variables in place and you are likely to end up with a core dump sooner or later. To get things to work smoothly you must do the following:

1. Call `mysql_library_init()` before any other MySQL functions. It is not thread-safe, so call it before threads are created, or protect the call with a mutex.
2. Arrange for `mysql_thread_init()` to be called early in the thread handler before calling any MySQL function. If you call `mysql_init()`, they will call `mysql_thread_init()` for you.
3. In the thread, call `mysql_thread_end()` before calling `pthread_exit()`. This frees the memory used by MySQL thread-specific variables.

The preceding notes regarding `mysql_init()` also apply to `mysql_connect()`, which calls `mysql_init()`.

If “undefined symbol” errors occur when linking your client with `libmysqlclient_r`, in most cases this is because you haven't included the thread libraries on the link/compile command.

## 28.3. MySQL PHP API

PHP is a server-side, HTML-embedded scripting language that may be used to create dynamic Web pages. It is available for most operating systems and Web servers, and can access most common databases, including MySQL. PHP may be run as a separate program or compiled as a module for use with the Apache Web server.

PHP actually provides two different MySQL API extensions:

- `mysql`: Available for PHP versions 4 and 5, this extension is intended for use with MySQL versions prior to MySQL 4.1. This extension does not support the improved authentication protocol used in MySQL 4.1, nor does it support prepared statements or multiple statements. If you wish to use this extension with MySQL 4.1, you will likely want to configure the MySQL server to use the `--old-passwords` option (see Section B.1.2.4, “Client does not support authentication protocol”). This extension is documented on the PHP Web site at <http://php.net/mysql>.
- `mysqli` - Stands for “MySQL, Improved”; this extension is available only in PHP 5. It is intended for use with MySQL 4.1.1 and later. This extension fully supports the authentication protocol used in MySQL 5.0, as well as the Prepared Statements and Multiple Statements APIs. In addition, this extension provides an advanced, object-oriented programming interface. You can read the documentation for the `mysqli` extension at <http://php.net/mysqli>. A helpful article can be found at <http://www.zend.com/php5/articles/php5-mysqli.php>.

If you're experiencing problems with enabling both the `mysql` and the `mysqli` extension when building PHP on Linux yourself, see Section 28.3.2, “Enabling Both `mysql` and `mysqli` in PHP”.

The PHP distribution and documentation are available from the [PHP Web site](#). MySQL provides the `mysql` and `mysqli` extensions for the Windows operating system on <http://dev.mysql.com/downloads/connector/php/>. You can find information why you should preferably use the extensions provided by MySQL on that page.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about MySQL and PHP in the Knowledge Base articles found at [PHP](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/knowledgebase.html>.

### 28.3.1. Common Problems with MySQL and PHP

- **Error: Maximum Execution Time Exceeded:** This is a PHP limit; go into the `php.ini` file and set the maximum execution time up from 30 seconds to something higher, as needed. It is also not a bad idea to double the RAM allowed per script to 16MB instead of 8MB.
- **Fatal error: Call to unsupported or undefined function mysql\_connect() in ...:** This means that your PHP version isn't compiled with MySQL support. You can either compile a dynamic MySQL module and load it into PHP or recompile PHP with built-in MySQL support. This process is described in detail in the PHP manual.
- **Error: Undefined reference to 'uncompress':** This means that the client library is compiled with support for a compressed client/server protocol. The fix is to add `-lz` last when linking with `-lmysqlclient`.
- **Error: Client does not support authentication protocol:** This is most often encountered when trying to use the older `mysql` extension with MySQL 4.1.1 and later. Possible solutions are: downgrade to MySQL 4.0; switch to PHP 5 and the newer `mysqli` extension; or configure the MySQL server with `--old-passwords`. (See [Section B.1.2.4](#), “Client does not support authentication protocol”, for more information.)

Those with PHP4 legacy code can make use of a compatibility layer for the old and new MySQL libraries, such as this one: <http://www.coggeshall.org/oss/mysqli2i>.

### 28.3.2. Enabling Both `mysql` and `mysqli` in PHP

If you're experiencing problems with enabling both the `mysql` and the `mysqli` extension when building PHP on Linux yourself, you should try the following procedure.

1. Configure PHP like this:

```
./configure --with-mysqli=/usr/bin/mysql_config --with-mysql=/usr
```

2. Edit the `Makefile` and search for a line that starts with `EXTRA_LIBS`. It might look like this (all on one line):

```
EXTRA_LIBS = -lcrypt -lcrypt -lmysqlclient -lz -lresolv -lm -ldl -lnsl
-lxml2 -lz -lm -lxml2 -lz -lm -lmysqlclient -lz -lcrypt -lnsl -lm
-lxml2 -lz -lm -lcrypt -lxml2 -lz -lm -lcrypt
```

Remove all duplicates, so that the line looks like this (all on one line):

```
EXTRA_LIBS = -lcrypt -lcrypt -lmysqlclient -lz -lresolv -lm -ldl -lnsl
-lxml2
```

3. Build and install PHP:

```
make
make install
```

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about the `mysqli` extension in the Knowledge Base articles found at [mysqli](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

## 28.4. MySQL Perl API

The Perl `DBI` module provides a generic interface for database access. You can write a DBI script that works with many different

database engines without change. To use DBI, you must install the `DBI` module, as well as a DataBase Driver (DBD) module for each type of server you want to access. For MySQL, this driver is the `DBD::mysql` module.

Perl DBI is the recommended Perl interface. It replaces an older interface called `mysqlperl`, which should be considered obsolete.

Installation instructions for Perl DBI support are given in [Section 2.15, “Perl Installation Notes”](#).

DBI information is available at the command line, online, or in printed form:

- Once you have the `DBI` and `DBD::mysql` modules installed, you can get information about them at the command line with the `perldoc` command:

```
shell> perldoc DBI
shell> perldoc DBI:FAQ
shell> perldoc DBD:mysql
```

You can also use `pod2man`, `pod2html`, and so forth to translate this information into other formats.

- For online information about Perl DBI, visit the DBI Web site, <http://dbi.perl.org/>. That site hosts a general DBI mailing list. MySQL AB hosts a list specifically about `DBD::mysql`; see [Section 1.6.1, “MySQL Mailing Lists”](#).
- For printed information, the official DBI book is *Programming the Perl DBI* (Alligator Descartes and Tim Bunce, O'Reilly & Associates, 2000). Information about the book is available at the DBI Web site, <http://dbi.perl.org/>.

For information that focuses specifically on using DBI with MySQL, see *MySQL and Perl for the Web* (Paul DuBois, New Riders, 2001). This book's Web site is <http://www.kitebird.com/mysql-perl/>.

## 28.5. MySQL C++ API

`MySQL++` is a MySQL API for C++. Warren Young has taken over this project. More information can be found at <http://tangentsoft.net/mysql++/doc>.

### MySQL Enterprise

MySQL Enterprise subscribers will find more information about using C++ with the MySQL API in the MySQL Knowledge Base. articles found at [C++](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

## 28.6. MySQL Python API

`MySQLdb` provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at <http://sourceforge.net/projects/mysql-python/>.

### MySQL Enterprise

MySQL Enterprise subscribers will find more information about using Python with the MySQL API in the MySQL Knowledge Base articles found at [Python](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

## 28.7. MySQL Tcl API

`MySQLtcl` is a simple API for accessing a MySQL database server from the Tcl programming language. It can be found at <http://www.xdobry.de/mysqltcl/>.

## 28.8. MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the Eiffel programming language, written by Michael Ravits. It can be found at <http://efsa.sourceforge.net/archive/ravits/mysql.htm>.

---

# Chapter 29. Connectors

This chapter describes MySQL Connectors, drivers that provide connectivity to the MySQL server for client programs. There are currently five MySQL Connectors:

- Connector/ODBC provides driver support for connecting to a MySQL server using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix and Mac OS X platforms.
- Connector/NET enables developers to create .NET applications that use data stored in a MySQL database. Connector/NET implements a fully-functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that want to use Connector/NET can be written in any of the supported .NET languages.
- The MySQL Visual Studio Plugin works with Connector/NET and Visual Studio 2005. The plugin is a MySQL DDEX Provider, which means that you can use the schema and data manipulation tools within Visual Studio to create and edit objects within a MySQL database.
- Connector/J provides driver support for connecting to MySQL from a Java application using the standard Java Database Connectivity (JDBC) API.
- Connector/MXJ is a tool that enables easy deployment and management of MySQL server and database through your Java application.
- Connector/PHP is a Windows-only connector for PHP that provides the `mysql` and `mysql_i` extensions for use with MySQL 5.0.18 and later.

For information on connecting to a MySQL server using other languages and interfaces than those detailed above, including Perl, Python and PHP for other platforms and environments, please refer to the [Chapter 28, APIs and Libraries](#) chapter.

## 29.1. MySQL Connector/ODBC

The MySQL Connector/ODBC is the name for the family of MySQL ODBC drivers (previously called MyODBC drivers) that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. This reference covers Connector/ODBC 3.51 and Connector/ODBC 5.1. Both releases provide an ODBC compliant interface to MySQL Server.

MySQL Connector/ODBC provides both driver-manager based and native interfaces to the MySQL database, which full support for MySQL functionality, including stored procedures, transactions and, with Connector/ODBC 5.1, full Unicode compliance.

For more information on the ODBC API standard and how to use it, refer to <http://support.microsoft.com/kb/110093>.

The application development part of this reference assumes a good working knowledge of C, general DBMS knowledge, and finally, but not least, familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to <http://dev.mysql.com/doc/>.

Typically, you need to install Connector/ODBC only on Windows machines. For Unix and Mac OS X you can use the native MySQL network or named pipe to communicate with your MySQL database. You may need Connector/ODBC for Unix or Mac OS X if you have an application that requires an ODBC interface to communicate with the database. Applications that require ODBC to communicate with MySQL include ColdFusion, Microsoft Office, and Filemaker Pro.

### Key topics:

- For help installing Connector/ODBC see [Section 29.1.3, “Connector/ODBC Installation”](#).
- For information on the configuration options, see [Section 29.1.4.2, “Connector/ODBC Connection Parameters”](#).
- For more information on connecting to a MySQL database from a Windows host using Connector/ODBC see [Section 29.1.5.2, “Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC”](#).
- If you want to use Microsoft Access as an interface to a MySQL database using Connector/ODBC see [Section 29.1.5.4, “Using Connector/ODBC with Microsoft Access”](#).
- General tips on using Connector/ODBC, including obtaining the last auto-increment ID see [Section 29.1.7.1, “Connector/ODBC General Functionality”](#).
- For tips and common questions on using Connector/ODBC with specific application see [Section 29.1.7.2, “Connector/ODBC Application Specific Tips”](#).

- For a general list of Frequently Asked Questions see [Section 29.1.7.3, “Connector/ODBC Errors and Resolutions \(FAQ\)”](#).
- Additional support when using Connector/ODBC is available, see [Section 29.1.8, “Connector/ODBC Support”](#).

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about MySQL and ODBC in the Knowledge Base articles about [ODBC](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

### 29.1.1. Connector/ODBC Versions

There are currently two version of Connector/ODBC available:

- Connector/ODBC 5.1, currently in Beta status, is a partial rewrite of the of the 3.51 code base and is designed to work all versions of MySQL from 4.1. Connector/ODBC 5.1 will be a complete implementation of the ODBC Core interface, plus more Level 1 and Level 2 functionality of the ODBC specification than that currently supported by Connector/ODBC 3.51. See [Section 29.1.2.1, “Connector/ODBC Roadmap”](#).

Connector/ODBC 5.1 also includes the following changes and improvements over the 3.51 release:

- Improved support on Windows 64-bit platforms.
- Full Unicode support at the driver level. This includes support for the [SQL\\_WCHAR](#) datatype, and support for Unicode login, password and DSN configurations. For more information, see [Microsoft Knowledgebase Article #716246](#).
- Support for the [SQL\\_NUMERIC\\_STRUCT](#) datatype, which provides easier access to the precise definition of numeric values. For more information, see [Microsoft Knowledgebase Article #714556](#)
- Native Windows setup library. This replaces the Qt library based interface for configuring DSN information within the ODBC Data Sources application.
- Support for the ODBC descriptor, which improves the handling and metadata of columns and parameter data. For more information, see [Microsoft Knowledgebase Article #716339](#).
- Connector/ODBC 3.51 is the current release of the 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. Connector/ODBC 3.51 has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) in order to continue to provide all functionality of ODBC for accessing MySQL.

The manual for versions of Connector/ODBC older than 3.51 can be located in the corresponding binary or source distribution. Please note that versions of Connector/ODBC earlier than the 3.51 revision were not fully compliant with the ODBC specification.

#### Note

Development on Connector/ODBC 5.0 was stopped due to development issues. Connector/ODBC 5.1 is now the current development release.

#### Note

From this section onward, the primary focus of this guide is the Connector/ODBC 3.51 and Connector/ODBC 5.1 drivers.

#### Note

Version numbers for MySQL products are formatted as X.X.X. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.XX.XX. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

### 29.1.2. Connector/ODBC Introduction

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that allows connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to <http://support.microsoft.com/kb/110093>.

### 29.1.2.1. Connector/ODBC Roadmap

Connector/ODBC 5.1 is currently in development and will be a complete implementation of the ODBC Core interface, plus more Level 1 and Level 2 functionality of the ODBC specification than that currently supported by Connector/ODBC 3.51.

The following functionality was added or changed as part of 5.1:

- Add support for SQL\_NUMERIC\_STRUCT: [MSDN Article 714556](#).
- Replace installer library with new implementation (from v5 tree).
- Implement native Windows setup library.
- Implement SQLCancel() ([Bug#15601](#)): [MSDN Article 714112](#).

The following functionality will be added in a version after 5.1:

- Implement native Mac OS X setup library.
- Replace OPTIONS flags with individual DSN settings (but support OPTIONS for backwards-compatibility).
- Fix support for SQLBIGINT ([Bug#28887](#)): [MSDN Article 714121](#).
- Make diagnostics support standards-compliant: [MSDN Article 711021](#).
- Add support for SQL\_ATTR\_METADATA\_ID: [MSDN Article 716447](#).
- Implement SQLBrowseConnect(): [MSDN Article 714565](#), [MSDN Article 712446](#).
- Implement arrays of parameters: [MSDN Article 711818](#).

### 29.1.2.2. General Information About ODBC and Connector/ODBC

Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by Connector/ODBC is given at [Section 29.1.6.1, "Connector/ODBC API Reference"](#). For general information about ODBC, see <http://support.microsoft.com/kb/110093>.

#### 29.1.2.2.1. Connector/ODBC Architecture

The Connector/ODBC architecture is based on five components, as shown in the following diagram:

- **Application:**

The Application uses the ODBC API to access the data from the MySQL server. The ODBC API in turn uses the communicates with the Driver Manager. The Application communicates with the Driver Manager using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

- Selecting the MySQL server and connecting to it
- Submitting SQL statements for execution
- Retrieving results (if any)
- Processing errors
- Committing or rolling back the transaction enclosing the SQL statement
- Disconnecting from the MySQL server

Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

- Resolves Data Source Names (DSN). The DSN is a configuration string that identifies a given database driver, database, database host and optionally authentication information that enables an ODBC application to connect to a database using a standardized reference.

Because the database connectivity information is identified by the DSN, any ODBC compliant application can connect to the data source using the same DSN reference. This eliminates the need to separately configure each application that needs access to a given database; instead you instruct the application to use a pre-configured DSN.

- Loading and unloading of the driver required to access a specific database as defined within the DSN. For example, if you have configured a DSN that connects to a MySQL database then the driver manager will load the Connector/ODBC driver to enable the ODBC API to communicate with the MySQL host.
- Processes ODBC function calls or passes them to the driver for processing.

- **Connector/ODBC Driver:**

The Connector/ODBC driver is a library that implements the functions supported by the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by MySQL.

- **DSN Configuration:**

The ODBC configuration file stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded according to the definition in the DSN. The driver uses this to read connection parameters based on the DSN specified. For more information, [Section 29.1.4, “Connector/ODBC Configuration”](#).

- **MySQL Server:**

The MySQL database where the information is stored. The database is used as the source of the data (during queries) and the destination for data (during inserts and updates).

### 29.1.2.2.2. ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC-aware application and any drivers. Its main functionality includes:

- Resolving Data Source Names (DSN).
- Driver loading and unloading.
- Processing ODBC function calls or passing them to the driver.

Both Windows and Mac OS X include ODBC driver managers with the operating system. Most ODBC Driver Manager implementations also include an administration application that makes the configuration of DSN and drivers easier. Examples and information on these managers, including Unix ODBC driver managers are listed below:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), <http://support.microsoft.com/kb/110093>.
- Mac OS X includes [ODBC Administrator](#), a GUI application that provides a simpler configuration mechanism for the Unix iODBC Driver Manager. You can configure DSN and driver information either through ODBC Administrator or through the iODBC configuration files. This also means that you can test ODBC Administrator configurations using the `iodbctest` command. <http://www.apple.com>.
- [unixODBC Driver Manager for Unix](#) (`libodbc.so`). See <http://www.unixodbc.org>, for more information. The [unixODBC Driver Manager](#) includes the Connector/ODBC driver 3.51 in the installation package, starting with version [unixODBC 2.1.2](#).
- [iODBC ODBC Driver Manager for Unix](#) (`libiodbc.so`), see <http://www.iodbc.org>, for more information.

### 29.1.3. Connector/ODBC Installation

You can install the Connector/ODBC drivers using two different methods, a binary installation and a source installation. The binary

installation is the easiest and most straightforward method of installation. Using the source installation methods should only be necessary on platforms where a binary installation package is not available, or in situations where you want to customize or modify the installation process or Connector/ODBC drivers before installation.

### Where to Get Connector/ODBC

MySQL AB distributes all its products under the General Public License (GPL). You can get a copy of the latest version of Connector/ODBC binaries and sources from the MySQL AB Web site <http://dev.mysql.com/downloads/>.

For more information about Connector/ODBC, visit <http://www.mysql.com/products/myodbc/>.

For more information about licensing, visit <http://www.mysql.com/company/legal/licensing/>.

### Supported Platforms

Connector/ODBC can be used on all major platforms supported by MySQL. You can install it on:

- Windows 95, 98, Me, NT, 2000, XP, and 2003
- All Unix-like Operating Systems, including: AIX, Amiga, BSDI, DEC, FreeBSD, HP-UX 10/11, Linux, NetBSD, OpenBSD, OS/2, SGI Irix, Solaris, SunOS, SCO OpenServer, SCO UnixWare, Tru64 Unix
- Mac OS X and Mac OS X Server

Using a binary distribution offers the most straightforward method for installing Connector/ODBC. If you want more control over the driver, the installation location and or to customize elements of the driver you will need to build and install from the source.

If a binary distribution is not available for a particular platform build the driver from the original source code. You can contribute the binaries you create to MySQL by sending a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com), so that it becomes available for other users.

For further instructions:

| Platform   | Binary                                    | Source                             |
|------------|-------------------------------------------|------------------------------------|
| Windows    | <a href="#">Installation Instructions</a> | <a href="#">Build Instructions</a> |
| Unix/Linux | <a href="#">Installation Instructions</a> | <a href="#">Build Instructions</a> |
| Mac OS X   | <a href="#">Installation Instructions</a> |                                    |

## 29.1.3.1. Installing Connector/ODBC from a Binary Distribution on Windows

Before installing the Connector/ODBC drivers on Windows you should ensure that your Microsoft Data Access Components (MDAC) are up to date. You can obtain the latest version from the [Microsoft Data Access and Storage](#) Web site.

There are three available distribution types to use when installing for Windows. The contents in each case are identical, it is only the installation method which is different.

- Zipped installer consists of a Zipped package containing a standalone installation application. To install from this package, you must unzip the installer, and then run the installation application. See [Section 29.1.3.1.1, “Installing the Windows Connector/ODBC Driver using an installer”](#) to complete the installation.
- MSI installer, an installation file that can be used with the installer included in Windows 2000, Windows XP and Windows Server 2003. See [Section 29.1.3.1.1, “Installing the Windows Connector/ODBC Driver using an installer”](#) to complete the installation.
- Zipped DLL package, containing the DLL files that need must be manually installed. See [Section 29.1.3.1.2, “Installing the Windows Connector/ODBC Driver using the Zipped DLL package”](#) to complete the installation.

### Note

An OLEDB/ODBC driver for Windows 64-bit is available from [Microsoft Downloads](#).

### 29.1.3.1.1. Installing the Windows Connector/ODBC Driver using an installer

The installer packages offer a very simple method for installing the Connector/ODBC drivers. If you have downloaded the zipped

installer then you must extract the installer application. The basic installation process is identical for both installers.

You should follow these steps to complete the installation:

1. Double click on the standalone installer that you extracted, or the MSI file you downloaded.
2. The MySQL Connector/ODBC 3.51 - Setup Wizard will start. Click the NEXT button to begin the installation process.

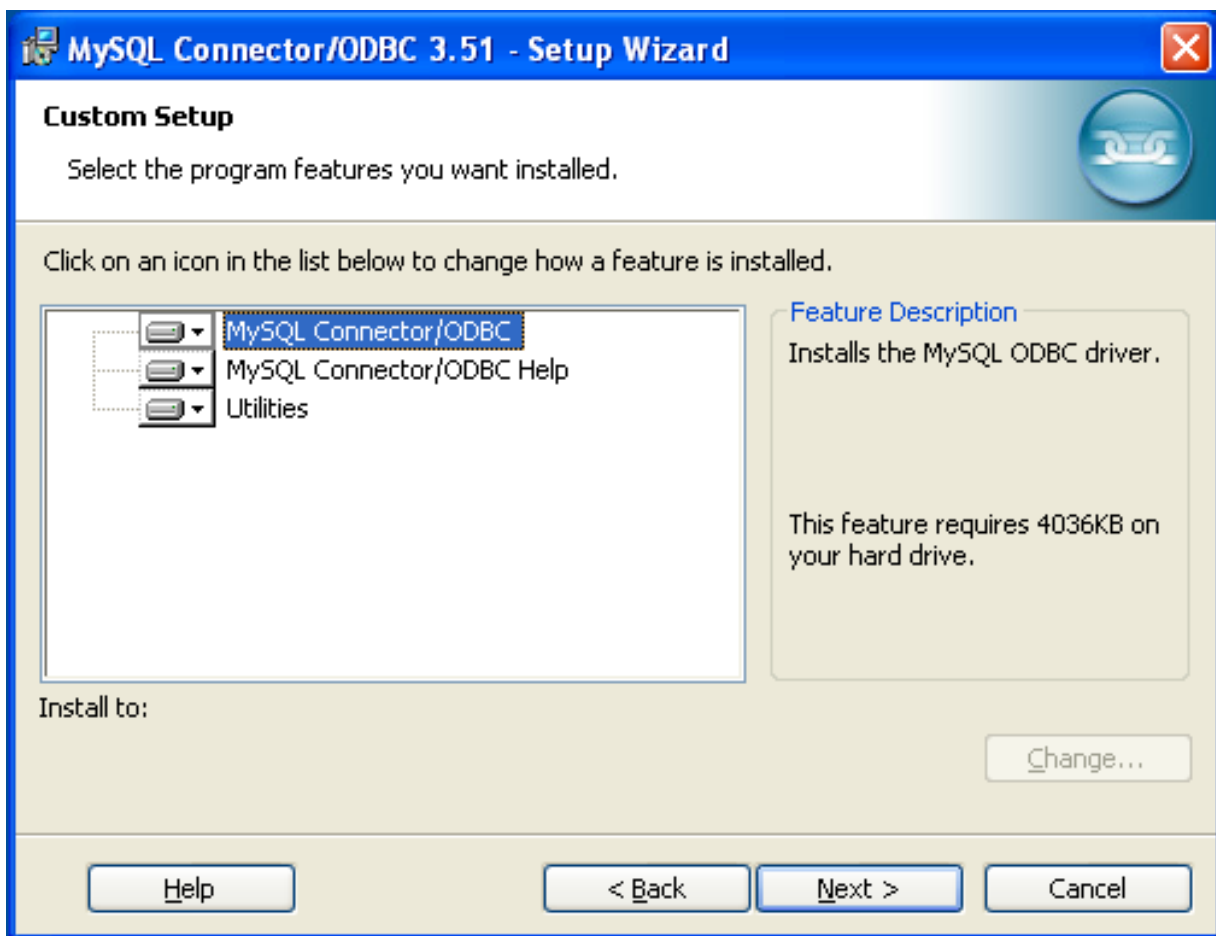

3. You will need to choose the installation type. The Typical installation provides the standard files you will need to connect to a MySQL database using ODBC. The Complete option installs all the available files, including debug and utility components. It is recommended you choose one of these two options to complete the installation. If choose one of these methods, click NEXT and then proceed to step 5.

You may also choose a Custom installation, which enables you to select the individual components that you want to install. You have chosen this method, click NEXT and then proceed to step 4.

4. If you have chosen a custom installation, use the pop-ups to select which components to install and then click NEXT to install the necessary files.

5. Once the files have copied to your machine, the installation is complete. Click FINISH to exit the installer.

Now the installation is complete, you can continue to configure your ODBC connections using [Section 29.1.4, “Connector/ODBC Configuration”](#).

### 29.1.3.1.2. Installing the Windows Connector/ODBC Driver using the Zipped DLL package

If you have downloaded the Zipped DLL package then you must install the individual files required for Connector/ODBC operation manually. Once you have unzipped the installation files, you can either perform this operation by hand, executing each statement individually, or you can use the included Batch file to perform an installation to the default locations.

To install using the Batch file:

1. Unzip the Connector/ODBC Zipped DLL package.
2. Open a Command Prompt.
3. Change to the directory created when you unzipped the Connector/ODBC Zipped DLL package.
4. Run `Install.bat`:

```
c:\> Install.bat
```

This will copy the necessary files into the default location, and then register the Connector/ODBC driver with the Windows ODBC manager.

If you want to copy the files to an alternative location - for example, to run or test different versions of the Connector/ODBC driver on the same machine, then you must copy the files by hand. It is however not recommended to install these files in a non-standard location. To copy the files by hand to the default installation location use the following steps:

1. Unzip the Connector/ODBC Zipped DLL package.

2. Open a Command Prompt.
3. Change to the directory created when you unzipped the Connector/ODBC Zipped DLL package.
4. Copy the library files to a suitable directory. The default is to copy them into the default Windows system directory `\Windows\System32`:

```
C:\> copy lib\myodbc3S.dll \Windows\System32
C:\> copy lib\myodbc3S.lib \Windows\System32
C:\> copy lib\myodbc3.dll \Windows\System32
C:\> copy lib\myodbc3.lib \Windows\System32
```

5. Copy the Connector/ODBC tools. These must be placed into a directory that is in the system `PATH`. The default is to install these into the Windows system directory `\Windows\System32`:

```
C:\> copy bin\myodbc3i.exe \Windows\System32
C:\> copy bin\myodbc3m.exe \Windows\System32
C:\> copy bin\myodbc3c.exe \Windows\System32
```

6. Optionally copy the help files. For these files to be accessible through the help system, they must be installed in the Windows system directory:

```
C:\> copy doc*.hlp \Windows\System32
```

7. Finally, you must register the Connector/ODBC driver with the ODBC manager:

```
C:\> myodbc3i -a -d -t"MySQL ODBC 3.51 Driver;\
DRIVER=myodbc3.dll;SETUP=myodbc3S.dll"
```

You must change the references to the DLL files and command location in the above statement if you have not installed these files into the default location.

## 29.1.3.2. Installing Connector/ODBC from a Binary Distribution on Unix

There are two methods available for installing Connector/ODBC on Unix from a binary distribution. For most Unix environments you will need to use the tarball distribution. For Linux systems, there is also an RPM distribution available.

### 29.1.3.2.1. Installing Connector/ODBC from a Binary Tarball Distribution

To install the driver from a tarball distribution (`.tar.gz` file), download the latest version of the driver for your operating system and follow these steps that demonstrate the process using the Linux version of the tarball:

```
shell> su root
shell> gunzip mysql-connector-odbc-3.51.11-i686-pc-linux.tar.gz
shell> tar xvf mysql-connector-odbc-3.51.11-i686-pc-linux.tar
shell> cd mysql-connector-odbc-3.51.11-i686-pc-linux
```

Read the installation instructions in the `INSTALL-BINARY` file and execute these commands.

```
shell> cp libmyodbc* /usr/local/lib
shell> cp odbc.ini /usr/local/etc
shell> export ODBCINI=/usr/local/etc/odbc.ini
```

Then proceed on to [Section 29.1.4.5, "Configuring a Connector/ODBC DSN on Unix"](#), to configure the DSN for Connector/ODBC. For more information, refer to the `INSTALL-BINARY` file that comes with your distribution.

### 29.1.3.2.2. Installing Connector/ODBC from an RPM Distribution

To install or upgrade Connector/ODBC from an RPM distribution on Linux, simply download the RPM distribution of the latest version of Connector/ODBC and follow the instructions below. Use `su root` to become `root`, then install the RPM file.

If you are installing for the first time:

```
shell> su root
shell> rpm -ivh mysql-connector-odbc-3.51.12.i386.rpm
```

If the driver exists, upgrade it like this:

```
shell> su root
shell> rpm -Uvh mysql-connector-odbc-3.51.12.i386.rpm
```

If there is any dependency error for MySQL client library, `libmysqlclient`, simply ignore it by supplying the `--nodeps` option, and then make sure the MySQL client shared library is in the path or set through `LD_LIBRARY_PATH`.

This installs the driver libraries and related documents to `/usr/local/lib` and `/usr/share/doc/MyODBC`, respectively. Proceed onto [Section 29.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#).

To **uninstall** the driver, become `root` and execute an `rpm` command:

```
shell> su root
shell> rpm -e mysql-connector-odbc
```

### 29.1.3.3. Installing Connector/ODBC from a Binary Distribution on Mac OS X

Mac OS X is based on the FreeBSD operating system, and you can normally use the MySQL network port for connecting to MySQL servers on other hosts. Installing the Connector/ODBC driver enables you to connect to MySQL databases on any platform through the ODBC interface. You should only need to install the Connector/ODBC driver when your application requires an ODBC interface. Applications that require or can use ODBC (and therefore the Connector/ODBC driver) include ColdFusion, Filemaker Pro, 4th Dimension and many other applications.

Mac OS X includes its own ODBC manager, based on the `iODBC` manager. Mac OS X includes an administration tool that provides easier administration of ODBC drivers and configuration, updating the underlying `iODBC` configuration files.

The method for installing Connector/ODBC on Mac OS X depends on the version on Connector/ODBC you are using. For Connector/ODBC 3.51.14 and later, the package is provided as a compress tar archive that you must manually install. For Connector/ODBC 3.51.13 and earlier the software was provided on a compressed disk image (`.dmg`) file and included an installer.

In either case, the driver is designed to work with the `iODBC` driver manager included with Mac OS X.

To install Connector/ODBC 3.51.14 and later:

1. Download the installation file. Note that versions are available for both PowerPC and Intel platforms.
2. Extract the archive:

```
$ tar xzf mysql-connector-odbc-3.51.16-osx10.4-x86-32bit.tar.gz
```

3. The directory created will contain two subdirectories, `lib` and `bin`. You need to copy these to a suitable location such as `/usr/local`:

```
$ cp bin/* /usr/local/bin
$ cp lib/* /usr/local/lib
```

4. Finally, you must register the driver with `iODBC` using the `myodbc3i` tool you just installed:

```
$ myodbc3i -a -d -t"MySQL ODBC 3.51 Driver;Driver=/usr/local/lib/libmyodbc3.so;Setup=/usr/local/lib/libmyodbc3S.so"
```

You can verify the installed drivers either by using the ODBC Administrator application or the `myodbc3i` utility:

```
$ myodbc3i -q -d
```

To install Connector/ODBC 3.51.13 and earlier, follow these steps:

1. Download the file to your computer and double-click on the downloaded image file.
2. Within the disk image you will find an installer package (with the `.pkg` extension). Double click on this file to start the Mac OS X installer.
3. You will be presented with the installer welcome message. Click the `CONTINUE` button to begin the installation process.

4. Please take the time to read the Important Information as it contains guidance on how to complete the installation process. Once you have read the notice and collected the necessary information, click CONTINUE.

- Connector/ODBC drivers are made available under the GNU General Public License. Please read the license if you are not familiar with it before continuing installation. Click CONTINUE to approve the license (you will be asked to confirm that decision) and continue the installation.

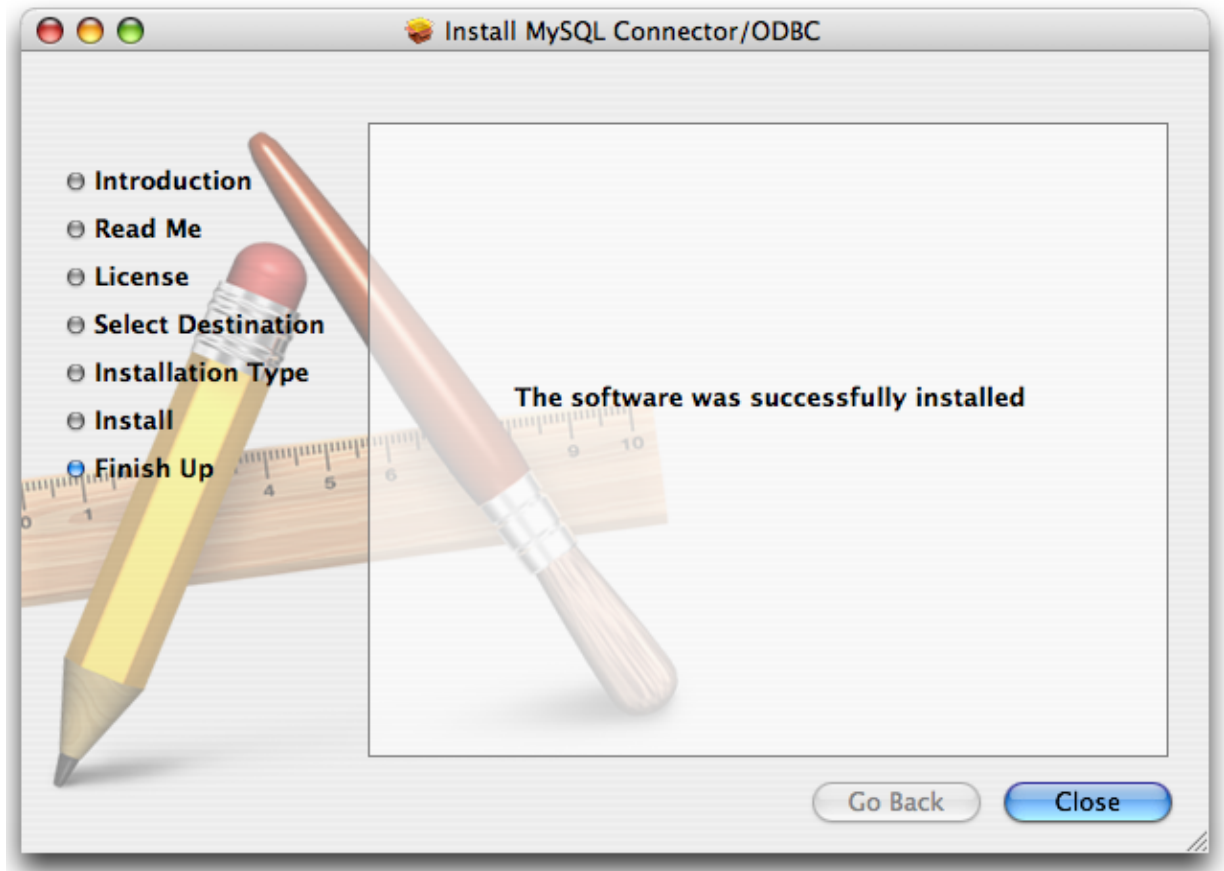

- Choose a location to install the Connector/ODBC drivers and the ODBC Administrator application. You must install the files onto a drive with an operating system and you may be limited in the choices available. Select the drive you want to use, and then click CONTINUE.

7. The installer will automatically select the files that need to be installed on your machine. Click **INSTALL** to continue. The installer will copy the necessary files to your machine. A progress bar will be shown indicating the installation progress.

8. When installation has been completed you will get a window like the one shown below. Click CLOSE to close and quit the installer.

#### 29.1.3.4. Installing Connector/ODBC from a Source Distribution on Windows

You should only need to install Connector/ODBC from source on Windows if you want to change or modify the source or installation. If you are unsure whether to install from source, please use the binary installation detailed in [Section 29.1.3.1, “Installing Connector/ODBC from a Binary Distribution on Windows”](#).

Installing Connector/ODBC from source on Windows requires a number of different tools and packages:

- MDAC, Microsoft Data Access SDK from <http://support.microsoft.com/kb/110093>.
- Suitable C compiler, such as Microsoft Visual C++ or the C compiler included with Microsoft Visual Studio.
- Compatible `make` tool. Microsoft's `nmake` is used in the examples in this section.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

##### 29.1.3.4.1. Building Connector/ODBC 3.51

Connector/ODBC source distributions include `Makefiles` that require the `nmake` or other `make` utility. In the distribution, you can find `Makefile` for building the release version and `Makefile_debug` for building debugging versions of the driver libraries and DLLs.

To build the driver, use this procedure:

1. Download and extract the sources to a folder, then change directory into that folder. The following command assumes the folder is named `myodbc3-src`:

```
C:\> cd myodbc3-src
```

2. Edit `Makefile` to specify the correct path for the MySQL client libraries and header files. Then use the following commands to build and install the release version:

```
C:\> nmake -f Makefile
C:\> nmake -f Makefile install
```

`nmake -f Makefile` builds the release version of the driver and places the binaries in subdirectory called `Release`.

`nmake -f Makefile install` installs (copies) the driver DLLs and libraries (`myodbc3.dll`, `myodbc3.lib`) to your system directory.

3. To build the debug version, use `Makefile_Debug` rather than `Makefile`, as shown below:

```
C:\> nmake -f Makefile_debug
C:\> nmake -f Makefile_debug install
```

4. You can clean and rebuild the driver by using:

```
C:\> nmake -f Makefile clean
C:\> nmake -f Makefile install
```

### Note

- Make sure to specify the correct MySQL client libraries and header files path in the Makefiles (set the `MYSQL_LIB_PATH` and `MYSQL_INCLUDE_PATH` variables). The default header file path is assumed to be `C:\mysql\include`. The default library path is assumed to be `C:\mysql\lib\opt` for release DLLs and `C:\mysql\lib\debug` for debug versions.
- For the complete usage of `nmake`, visit [http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv\\_vcce4/html/evgrfRunningNMAKE.asp](http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv_vcce4/html/evgrfRunningNMAKE.asp).
- If you are using the Subversion tree for compiling, all Windows-specific `Makefiles` are named as `Win_Makefile*`.

### 29.1.3.4.2. Testing

After the driver libraries are copied/installed to the system directory, you can test whether the libraries are properly built by using the samples provided in the `samples` subdirectory:

```
C:\> cd samples
C:\> nmake -f Makefile all
```

### 29.1.3.5. Installing Connector/ODBC from a Source Distribution on Unix

You need the following tools to build MySQL from source on Unix:

- A working ANSI C++ compiler. `gcc` 2.95.2 or later, SGI C++, and SunPro C++ are some of the compilers that are known to work.
- A good `make` program. GNU `make` is always recommended and is sometimes required.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

If you have built your own MySQL server and/or client libraries from source then you must have used the `-enable-thread-safe-client` option to `configure` when the libraries were built.

You should also ensure that the `libmysqlclient` library were built and installed as a shared library.

- A compatible ODBC manager must be installed. Connector/ODBC is known to work with the `iODBC` and `unixODBC` managers. See [Section 29.1.2.2.2, “ODBC Driver Managers”](#), for more information.
- If you are using a character set that isn't compiled into the MySQL client library then you need to install the MySQL character

definitions from the `charsets` directory into `SHAREDIR` (by default, `/usr/local/mysql/share/mysql/charsets`). These should be in place if you have installed the MySQL server on the same machine. See [Section 9.1, “Character Set Support”](#), for more information on character set support.

Once you have all the required files, unpack the source files to a separate directory, you then have to run `configure` and build the library using `make`.

### 29.1.3.5.1. Typical `configure` Options

The `configure` script gives you a great deal of control over how you configure your Connector/ODBC build. Typically you do this using options on the `configure` command line. You can also affect `configure` using certain environment variables. For a list of options and environment variables supported by `configure`, run this command:

```
shell> ./configure --help
```

Some of the more commonly used `configure` options are described here:

1. To compile Connector/ODBC, you need to supply the MySQL client include and library files path using the `--with-mysql-path=DIR` option, where `DIR` is the directory where MySQL is installed.

MySQL compile options can be determined by running `DIR/bin/mysql_config`.

2. Supply the standard header and library files path for your ODBC Driver Manager (`iODBC` or `unixODBC`).

- If you are using `iODBC` and `iODBC` is not installed in its default location (`/usr/local`), you might have to use the `--with-iodbc=DIR` option, where `DIR` is the directory where `iODBC` is installed.

If the `iODBC` headers do not reside in `DIR/include`, you can use the `--with-iodbc-includes=INCDIR` option to specify their location.

The applies to libraries. If they are not in `DIR/lib`, you can use the `--with-iodbc-libs=LIBDIR` option.

- If you are using `unixODBC`, use the `--with-unixODBC=DIR` option (case sensitive) to make `configure` look for `unixODBC` instead of `iODBC` by default, `DIR` is the directory where `unixODBC` is installed.

If the `unixODBC` headers and libraries aren't located in `DIR/include` and `DIR/lib`, use the `--with-unixODBC-includes=INCDIR` and `--with-unixODBC-libs=LIBDIR` options.

3. You might want to specify an installation prefix other than `/usr/local`. For example, to install the Connector/ODBC drivers in `/usr/local/odbc/lib`, use the `--prefix=/usr/local/odbc` option.

The final configuration command looks something like this:

```
shell> ./configure --prefix=/usr/local \
 --with-iodbc=/usr/local \
 --with-mysql-path=/usr/local/mysql
```

### 29.1.3.5.2. Additional `configure` Options

There are a number of other options that you need, or want, to set when configuring the Connector/ODBC driver before it is built.

- To link the driver with MySQL thread safe client libraries `libmysqlclient_r.so` or `libmysqlclient_r.a`, you must specify the following `configure` option:

```
--enable-thread-safe
```

and can be disabled (default) using

```
--disable-thread-safe
```

This option enables the building of the driver thread-safe library `libmyodbc3_r.so` from by linking with MySQL thread-safe client library `libmysqlclient_r.so` (The extensions are OS dependent).

If the compilation with the thread-safe option fails, it may be because the correct thread-libraries on the system could not be located. You should set the value of `LIBS` to point to the correct thread library for your system.

```
LIBS="-lpthread" ./configure ..
```

- You can enable or disable the shared and static versions of Connector/ODBC using these options:

```
--enable-shared[=yes/no]
--disable-shared
--enable-static[=yes/no]
--disable-static
```

- By default, all the binary distributions are built as non-debugging versions (configured with `--without-debug`).

To enable debugging information, build the driver from source distribution and use the `--with-debug` option when you run `configure`.

- This option is available only for source trees that have been obtained from the Subversion repository. This option does not apply to the packaged source distributions.

By default, the driver is built with the `--without-docs` option. If you would like the documentation to be built, then execute `configure` with:

```
--with-docs
```

### 29.1.3.5.3. Building and Compilation

To build the driver libraries, you have to just execute `make`.

```
shell> make
```

If any errors occur, correct them and continue the build process. If you aren't able to build, then send a detailed email to [<myodbc@lists.mysql.com>](mailto:<myodbc@lists.mysql.com>) for further assistance.

### 29.1.3.5.4. Building Shared Libraries

On most platforms, MySQL does not build or support `.so` (shared) client libraries by default. This is based on our experience of problems when building shared libraries.

In cases like this, you have to download the MySQL distribution and configure it with these options:

```
--without-server --enable-shared
```

To build shared driver libraries, you must specify the `--enable-shared` option for `configure`. By default, `configure` does not enable this option.

If you have configured with the `--disable-shared` option, you can build the `.so` file from the static libraries using the following commands:

```
shell> cd mysql-connector-odbc-3.51.01
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
 $CC -bundle -flat_namespace -undefined error \
 -o .libs/libmyodbc3-3.51.01.so \
 catalog.o connect.o cursor.o dll.o error.o execute.o \
 handle.o info.o misc.o myodbc3.o options.o prepare.o \
 results.o transact.o utility.o \
 -L/usr/local/mysql/lib/mysql/ \
 -L/usr/local/iodbc/lib/ \
 -lz -lc -lmysqlclient -liodbcinst
```

Make sure to change `-liodbcinst` to `-lodbcinst` if you are using `unixODBC` instead of `iODBC`, and configure the library paths accordingly.

This builds and places the `libmyodbc3-3.51.01.so` file in the `.libs` directory. Copy this file to the Connector/ODBC library installation directory (`/usr/local/lib` (or the `lib` directory under the installation directory that you supplied with the `-prefix`)).

```
shell> cd .libs
shell> cp libmyodbc3-3.51.01.so /usr/local/lib
shell> cd /usr/local/lib
shell> ln -s libmyodbc3-3.51.01.so libmyodbc3.so
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
 $CC -bundle -flat_namespace -undefined error
 -o .libs/libmyodbc3_r-3.51.01.so
 catalog.o connect.o cursor.o dll.o error.o execute.o
 handle.o info.o misc.o myodbc3.o options.o prepare.o
 results.o transact.o utility.o
 -L/usr/local/mysql/lib/mysql/
 -L/usr/local/iodbc/lib/
 -lz -lc -lmysqlclient_r -liodbcinst
```

### 29.1.3.5.5. Installing Driver Libraries

To install the driver libraries, execute the following command:

```
shell> make install
```

That command installs one of the following sets of libraries:

For Connector/ODBC 3.51:

- `libmyodbc3.so`
- `libmyodbc3-3.51.01.so`, where 3.51.01 is the version of the driver
- `libmyodbc3.a`

For thread-safe Connector/ODBC 3.51:

- `libmyodbc3_r.so`
- `libmyodbc3-3_r.51.01.so`
- `libmyodbc3_r.a`

For more information on build process, refer to the `INSTALL` file that comes with the source distribution. Note that if you are trying to use the `make` from Sun, you may end up with errors. On the other hand, GNU `gmake` should work fine on all platforms.

### 29.1.3.5.6. Testing Connector/ODBC on Unix

To run the basic samples provided in the distribution with the libraries that you built, use the following command:

```
shell> make test
```

Before running the tests, create the DSN 'myodbc3' in `odbc.ini` and set the environment variable `ODBCINI` to the correct `odbc.ini` file; and MySQL server is running. You can find a sample `odbc.ini` with the driver distribution.

You can even modify the `samples/run-samples` script to pass the desired DSN, UID, and PASSWORD values as the command-line arguments to each sample.

### 29.1.3.5.7. Building Connector/ODBC from Source on Mac OS X

To build the driver on Mac OS X (Darwin), make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
 --with-unixODBC=/usr/local
 --with-mysql-path=/usr/local/mysql
 --disable-shared
 --enable-gui=no
 --host=powerpc-apple
```

The command assumes that the `unixODBC` and MySQL are installed in the default locations. If not, configure accordingly.

On Mac OS X, `--enable-shared` builds `.dylib` files by default. You can build `.so` files like this:

```
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
 $CC -bundle -flat_namespace -undefined error
```

```
-o .libs/libmyodbc3-3.51.01.so *.o
-L/usr/local/mysql/lib/
-L/usr/local/iodbc/lib
-liodbcinst -lmysqlclient -lz -lc
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
$CC -bundle -flat_namespace -undefined error
-o .libs/libmyodbc3-3.51.01.so *.o
-L/usr/local/mysql/lib/
-L/usr/local/iodbc/lib
-liodbcinst -lmysqlclient_r -lz -lc -lpthread
```

Make sure to change the `-liodbcinst` to `-lodbcinst` in case of using `unixODBC` instead of `iODBC` and configure the libraries path accordingly.

In Apple's version of GCC, both `cc` and `gcc` are actually symbolic links to `gcc3`.

Copy this library to the `$prefix/lib` directory and symlink to `libmyodbc3.so`.

You can cross-check the output shared-library properties using this command:

```
shell> otool -LD .libs/libmyodbc3-3.51.01.so
```

### 29.1.3.5.8. Building Connector/ODBC from Source on HP-UX

To build the driver on HP-UX 10.x or 11.x, make use of the following `configure` example:

If using `cc`:

```
shell> CC="cc" \
CFLAGS="+z" \
LDFLAGS="-Wl,+b:-Wl,+s" \
./configure --prefix=/usr/local
--with-unixodbc=/usr/local
--with-mysql-path=/usr/local/mysql/lib/mysql
--enable-shared
--enable-thread-safe
```

If using `gcc`:

```
shell> CC="gcc" \
LDFLAGS="-Wl,+b:-Wl,+s" \
./configure --prefix=/usr/local
--with-unixodbc=/usr/local
--with-mysql-path=/usr/local/mysql
--enable-shared
--enable-thread-safe
```

Once the driver is built, cross-check its attributes using `chatr .libs/libmyodbc3.sl` to determine whether you need to have set the MySQL client library path using the `SHLIB_PATH` environment variable. For static versions, ignore all shared-library options and run `configure` with the `--disable-shared` option.

### 29.1.3.5.9. Building Connector/ODBC from Source on AIX

To build the driver on AIX, make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
--with-unixodbc=/usr/local
--with-mysql-path=/usr/local/mysql
--disable-shared
--enable-thread-safe
```

#### Note

For more information about how to build and set up the static and shared libraries across the different platforms refer to ['Using static and shared libraries across platforms'](#).

### 29.1.3.6. Installing Connector/ODBC from the Development Source Tree

#### Caution

You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL Connector/ODBC up and running on your system, you should use a standard release distribution.

To be able to access the Connector/ODBC source tree, you must have Subversion installed. Subversion is freely available from <http://subversion.tigris.org/>.

To build from the source trees, you need the following tools:

- autoconf 2.52 (or newer)
- automake 1.4 (or newer)
- libtool 1.4 (or newer)
- m4

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To checkout out the Connector/ODBC sources, change to the directory where you want the copy of the Connector/ODBC tree to be stored, then use the following command:

```
shell> svn co http://svn.mysql.com/svnpublic/connector-odbc3
```

You should now have a copy of the entire Connector/ODBC source tree in the directory `connector-odbc3`. To build from this source tree on Unix or Linux follow these steps:

```
shell> cd connector-odbc3
shell> aclocal
shell> autoheader
shell> autoconf
shell> automake;
shell> ./configure # Add your favorite options here
shell> make
```

For more information on how to build, refer to the `INSTALL` file located in the same directory. For more information on options to `configure`, see [Section 29.1.3.5.1, “Typical configure Options”](#)

When the build is done, run `make install` to install the Connector/ODBC 3.51 driver on your system.

If you have gotten to the `make` stage and the distribution does not compile, please report it to [<myodbc@lists.mysql.com>](mailto:<myodbc@lists.mysql.com>).

On Windows, make use of Windows Makefiles `WIN-Makefile` and `WIN-Makefile_debug` in building the driver. For more information, see [Section 29.1.3.4, “Installing Connector/ODBC from a Source Distribution on Windows”](#).

After the initial checkout operation to get the source tree, you should run `svn update` periodically update your source according to the latest version.

## 29.1.4. Connector/ODBC Configuration

Before you connect to a MySQL database using the Connector/ODBC driver you must configure an ODBC *Data Source Name*. The DSN associates the various configuration parameters required to communicate with a database to a specific name. You use the DSN in an application to communicate with the database, rather than specifying individual parameters within the application itself. DSN information can be user specific, system specific, or provided in a special file. ODBC data source names are configured in different ways, depending on your platform and ODBC driver.

### 29.1.4.1. Data Source Names

A Data Source Name associates the configuration parameters for communicating with a specific database. Generally a DSN consists of the following parameters:

- Name
- Hostname
- Database Name
- Login
- Password

In addition, different ODBC drivers, including Connector/ODBC, may accept additional driver-specific options and parameters.

There are three types of DSN:

- A *System DSN* is a global DSN definition that is available to any user and application on a particular system. A System DSN can normally only be configured by a systems administrator, or by a user who has specific permissions that let them create System DSNs.
- A *User DSN* is specific to an individual user, and can be used to store database connectivity information that the user regularly uses.
- A *File DSN* uses a simple file to define the DSN configuration. File DSNs can be shared between users and machines and are therefore more practical when installing or deploying DSN information as part of an application across many machines.

DSN information is stored in different locations depending on your platform and environment.

### 29.1.4.2. Connector/ODBC Connection Parameters

You can specify the parameters in the following tables for Connector/ODBC when configuring a DSN. Users on Windows can use the Options and Advanced panels when configuring a DSN to set these parameters; see the table for information on which options relate to which fields and checkboxes. On Unix and Mac OS X, use the parameter name and value as the keyword/value pair in the DSN configuration. Alternatively, you can set these parameters within the `InConnectionString` argument in the `SQLDriverConnect()` call.

| Parameter              | Default Value          | Comment                                                                                                                                                                  |
|------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>user</code>      | ODBC                   | The username used to connect to MySQL.                                                                                                                                   |
| <code>uid</code>       | ODBC                   | Synonymous with <code>user</code> . Added in 3.51.16.                                                                                                                    |
| <code>server</code>    | <code>localhost</code> | The hostname of the MySQL server.                                                                                                                                        |
| <code>database</code>  |                        | The default database.                                                                                                                                                    |
| <code>option</code>    | 0                      | Options that specify how Connector/ODBC should work. See below.                                                                                                          |
| <code>port</code>      | 3306                   | The TCP/IP port to use if <code>server</code> is not <code>localhost</code> .                                                                                            |
| <code>stmt</code>      |                        | A statement to execute when connecting to MySQL.                                                                                                                         |
| <code>password</code>  |                        | The password for the <code>user</code> account on <code>server</code> .                                                                                                  |
| <code>pwd</code>       |                        | Synonymous with <code>password</code> . Added in 3.51.16.                                                                                                                |
| <code>socket</code>    |                        | The Unix socket file or Windows named pipe to connect to if <code>server</code> is <code>localhost</code> .                                                              |
| <code>sslca</code>     |                        | The path to a file with a list of trust SSL CAs. Added in 3.51.16.                                                                                                       |
| <code>sslcapath</code> |                        | The path to a directory that contains trusted SSL CA certificates in PEM format. Added in 3.51.16.                                                                       |
| <code>sslcert</code>   |                        | The name of the SSL certificate file to use for establishing a secure connection. Added in 3.51.16.                                                                      |
| <code>sslcipher</code> |                        | A list of allowable ciphers to use for SSL encryption. The cipher list has the same format as the <code>openssl ciphers</code> command. Added in 3.51.16.                |
| <code>sslkey</code>    |                        | The name of the SSL key file to use for establishing a secure connection. Added in 3.51.16.                                                                              |
| <code>charset</code>   |                        | The character set to use for the connection. Added in 3.51.17.                                                                                                           |
| <code>sslverify</code> |                        | If set to 1, the SSL certificate will be verified when used with the MySQL connection. If not set, then the default behaviour is to ignore SSL certificate verification. |

#### Note

The SSL configuration parameters can also be automatically loaded from a `my.ini` or `my.cnf` file.

The `option` argument is used to tell Connector/ODBC that the client isn't 100% ODBC compliant. On Windows, you normally select options by toggling the checkboxes in the connection screen, but you can also select them in the `option` argument. The following options are listed in the order in which they appear in the Connector/ODBC connect screen:

| Value | Flagname                      | GUI Option            | Description                                                  |
|-------|-------------------------------|-----------------------|--------------------------------------------------------------|
| 1     | <code>FLAG_FIELD_LENGT</code> | Don't Optimize Column | The client can't handle that Connector/ODBC returns the real |

|         |                        |                                           |                                                                                                                                                                                                                                                                                                                                            |
|---------|------------------------|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|         | H                      | Width                                     | width of a column. This option was removed in 3.51.18.                                                                                                                                                                                                                                                                                     |
| 2       | FLAG_FOUND_ROWS        | Return Matching Rows                      | The client can't handle that MySQL returns the true value of affected rows. If this flag is set, MySQL returns "found rows" instead. You must have MySQL 3.21.14 or newer to get this to work.                                                                                                                                             |
| 4       | FLAG_DEBUG             | Trace Driver Calls To myodbc.log          | Make a debug log in <code>C:\myodbc.log</code> on Windows, or <code>/tmp/myodbc.log</code> on Unix variants. This option was removed in Connector/ODBC 3.51.18.                                                                                                                                                                            |
| 8       | FLAG_BIG_PACKETS       | Allow Big Results                         | Don't set any packet limit for results and bind parameters. Without this option, parameter binding will be truncated to 255 characters.                                                                                                                                                                                                    |
| 16      | FLAG_NO_PROMPT         | Don't Prompt Upon Connect                 | Don't prompt for questions even if driver would like to prompt.                                                                                                                                                                                                                                                                            |
| 32      | FLAG_DYNAMIC_CURSOR    | Enable Dynamic Cursor                     | Enable or disable the dynamic cursor support.                                                                                                                                                                                                                                                                                              |
| 64      | FLAG_NO_SCHEMA         | Ignore # in Table Name                    | Ignore use of database name in <code>db_name.tbl_name.col_name</code> .                                                                                                                                                                                                                                                                    |
| 128     | FLAG_NO_DEFAULT_CURSOR | User Manager Cursors                      | Force use of ODBC manager cursors (experimental).                                                                                                                                                                                                                                                                                          |
| 256     | FLAG_NO_LOCALE         | Don't Use Set Locale                      | Disable the use of extended fetch (experimental).                                                                                                                                                                                                                                                                                          |
| 512     | FLAG_PAD_SPACE         | Pad Char To Full Length                   | Pad <code>CHAR</code> columns to full column length.                                                                                                                                                                                                                                                                                       |
| 1024    | FLAG_FULL_COLUMN_NAMES | Return Table Names for SQLDescribeCol     | <code>SQLDescribeCol()</code> returns fully qualified column names.                                                                                                                                                                                                                                                                        |
| 2048    | FLAG_COMPRESSED_PROTO  | Use Compressed Protocol                   | Use the compressed client/server protocol.                                                                                                                                                                                                                                                                                                 |
| 4096    | FLAG_IGNORE_SPACE      | Ignore Space After Function Names         | Tell server to ignore space after function name and before "(" (needed by PowerBuilder). This makes all function names keywords.                                                                                                                                                                                                           |
| 8192    | FLAG_NAMED_PIPE        | Force Use of Named Pipes                  | Connect with named pipes to a <code>mysqld</code> server running on NT.                                                                                                                                                                                                                                                                    |
| 16384   | FLAG_NO_BIGINT         | Change BIGINT Columns to Int              | Change <code>BIGINT</code> columns to <code>INT</code> columns (some applications can't handle <code>BIGINT</code> ).                                                                                                                                                                                                                      |
| 32768   | FLAG_NO_CATALOG        | No Catalog                                | Forces results from the catalog functions, such as <code>SQLTables</code> , to always return <code>NULL</code> and the driver to report that catalogs are not supported.                                                                                                                                                                   |
| 65536   | FLAG_USE_MYCNF         | Read Options From my.cnf                  | Read parameters from the <code>[client]</code> and <code>[odbc]</code> groups from <code>my.cnf</code> .                                                                                                                                                                                                                                   |
| 131072  | FLAG_SAFE              | Safe                                      | Add some extra safety checks.                                                                                                                                                                                                                                                                                                              |
| 262144  | FLAG_NO_TRANSACTIONS   | Disable transactions                      | Disable transactions.                                                                                                                                                                                                                                                                                                                      |
| 524288  | FLAG_LOG_QUERY         | Save queries to myodbc.sql                | Enable query logging to <code>c:\myodbc.sql(/tmp/myodbc.sql)</code> file. (Enabled only in debug mode.)                                                                                                                                                                                                                                    |
| 1048576 | FLAG_NO_CACHE          | Don't Cache Result (forward only cursors) | Do not cache the results locally in the driver, instead read from server ( <code>mysql_use_result()</code> ). This works only for forward-only cursors. This option is very important in dealing with large tables when you don't want the driver to cache the entire result set.                                                          |
| 2097152 | FLAG_FORWARD_CURSOR    | Force Use Of Forward Only Cursors         | Force the use of <code>Forward-only</code> cursor type. In case of applications setting the default static/dynamic cursor type, and one wants the driver to use non-cache result sets, then this option ensures the forward-only cursor behavior.                                                                                          |
| 4194304 | FLAG_AUTO_RECONNECT    | Enable auto-reconnect.                    | Enables auto-reconnection functionality. You should not use this option with transactions, since a auto reconnection during a incomplete transaction may cause corruption. Note that an auto-reconnected connection will not inherit the same settings and environment as the original. This option was enabled in Connector/ODBC 3.51.13. |
| 8388608 | FLAG_AUTO_IS_NULL      | Flag Auto Is Null                         | When set, this option causes the connection to set the <code>SQL_AUTO_IS_NULL</code> option to 1. This disables the standard                                                                                                                                                                                                               |

|           |                                       |                                   |                                                                                                                                                                                                                                                                                                                                            |
|-----------|---------------------------------------|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |                                       |                                   | behavior, but may enable older applications to correctly identify <a href="#">AUTO_INCREMENT</a> values. For more information. See <a href="#">IS NULL</a> . This option was enabled in Connector/ODBC 3.51.13.                                                                                                                            |
| 16777216  | <a href="#">FLAG_ZERO_DATE_TO_MIN</a> | Flag Zero Date to Min             | Translates zero dates ( <a href="#">XXXX-00-00</a> ) into the minimum date values supported by ODBC, <a href="#">XXXX-01-01</a> . This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was enabled in Connector/ODBC 3.51.17.                |
| 33554432  | <a href="#">FLAG_MIN_DATE_TO_ZERO</a> | Flag Min Date to Zero             | Translates the minimum ODBC date value ( <a href="#">XXXX-01-01</a> ) to the zero date format supported by MySQL ( <a href="#">XXXX-00-00</a> ). This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was enabled in Connector/ODBC 3.51.17. |
| 67108864  | <a href="#">FLAG_MULTI_STATEMENTS</a> | Allow multiple statements         | Enables support for batched statements. This option was enabled in Connector/ODBC 3.51.18.                                                                                                                                                                                                                                                 |
| 134217728 | <a href="#">FLAG_COLUMN_SIZE_S32</a>  | Limit column size to 32-bit value | Limits the column size to a signed 32-bit value to prevent problems with larger column sizes in applications that do not support them. This option is automatically enabled when working with ADO applications. This option was enabled in Connector/ODBC 3.51.22.                                                                         |

To select multiple options, add together their values. For example, setting `option` to 12 (4+8) gives you debugging without packet limits.

The following table shows some recommended `option` values for various configurations:

| Configuration                                           | Option Value |
|---------------------------------------------------------|--------------|
| Microsoft Access, Visual Basic                          | 3            |
| Driver trace generation (Debug mode)                    | 4            |
| Microsoft Access (with improved DELETE queries)         | 35           |
| Large tables with too many rows                         | 2049         |
| Sybase PowerBuilder                                     | 135168       |
| Query log generation (Debug mode)                       | 524288       |
| Generate driver trace as well as query log (Debug mode) | 524292       |
| Large tables with no-cache results                      | 3145731      |

### 29.1.4.3. Configuring a Connector/ODBC DSN on Windows

The [ODBC Data Source Administrator](#) within Windows enables you to create DSNs, check driver installation and configure ODBC systems such as tracing (used for debugging) and connection pooling.

Different editions and versions of Windows store the [ODBC Data Source Administrator](#) in different locations depending on the version of Windows that you are using.

To open the [ODBC Data Source Administrator](#) in Windows Server 2003:

#### Tip

Because it is possible to create DSN using either the 32-bit or 64-bit driver, but using the same DNS identifier, it is advisable to include the driver being used within the DSN identifier. This will help you to identify the DSN when using it from applications such as Excel that are only compatible with the 32-bit driver. For example, you might add [Using32bitCODBC](#) to the DSN identifier for the 32-bit interface and [Using64bitCODBC](#) for those using the 64-bit Connector/ODBC driver.

1. On the [Start](#) menu, choose [Administrative Tools](#), and then click [Data Sources \(ODBC\)](#).

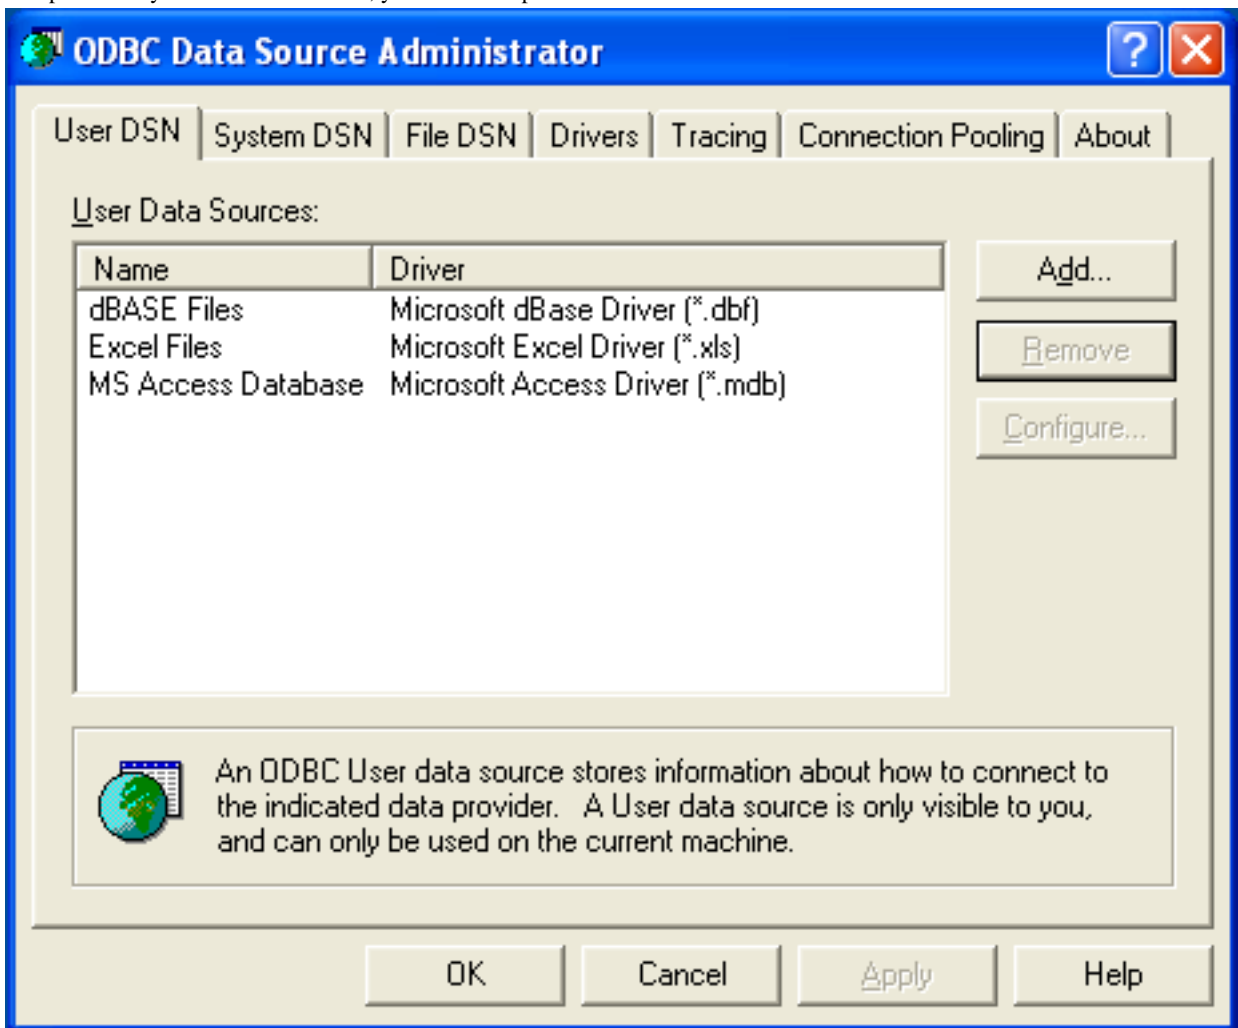

To open the [ODBC Data Source Administrator](#) in Windows 2000 Server or Windows 2000 Professional:

1. On the **Start** menu, choose **Settings**, and then click **Control Panel**.
2. In **Control Panel**, click **Administrative Tools**.
3. In **Administrative Tools**, click **Data Sources (ODBC)**.

To open the **ODBC Data Source Administrator** on Windows XP:

1. On the **Start** menu, click **Control Panel**.
2. In the **Control Panel** when in **Category View** click **Performance and Maintenance** and then click **Administrative Tools**. If you are viewing the **Control Panel** in **Classic View**, click **Administrative Tools**.
3. In **Administrative Tools**, click **Data Sources (ODBC)**.

Irrespective of your Windows version, you should be presented the **ODBC Data Source Administrator** window:

Within Windows XP, you can add the **Administrative Tools** folder to your **START** menu to make it easier to locate the **ODBC Data Source Administrator**. To do this:

1. Right click on the **START** menu.
2. Select **Properties**.
3. Click **CUSTOMIZE...**
4. Select the **ADVANCED** tab.

5. Within [Start menu items](#), within the [System Administrative Tools](#) section, select [Display on the All Programs menu](#).

Within both Windows Server 2003 and Windows XP you may want to permanently add the [ODBC Data Source Administrator](#) to your START menu. To do this, locate the [Data Sources \(ODBC\)](#) icon using the methods shown, then right-click on the icon and then choose [PIN TO START MENU](#).

The interfaces for the 3.51 and 5.1 versions of the Connector/ODBC driver are different, although the fields and information that you need to enter remain the same.

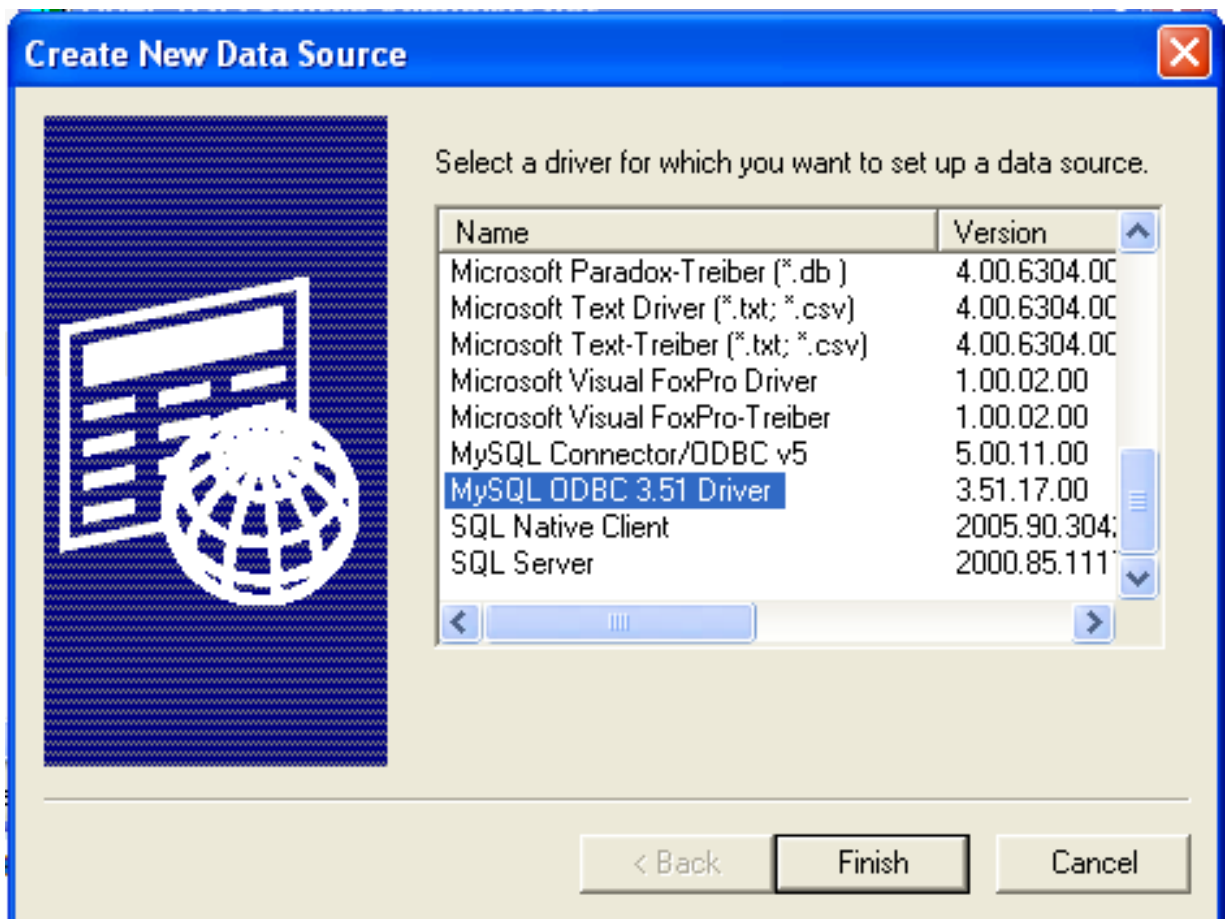

To configure a DSN using Connector/ODBC 3.51.x or Connector/ODBC 5.1.0, see [Section 29.1.4.3.1, “Configuring a Connector/ODBC 3.51 DSN on Windows”](#).

To configure a DSN using Connector/ODBC 5.1.1 or later, see [Section 29.1.4.3.2, “Configuring a Connector/ODBC 5.1 DSN on Windows”](#).

### 29.1.4.3.1. Configuring a Connector/ODBC 3.51 DSN on Windows

To add and configure a new Connector/ODBC data source on Windows, use the [ODBC Data Source Administrator](#):

1. Open the [ODBC Data Source Administrator](#).
2. To create a System DSN (which will be available to all users), select the [System DSN](#) tab. To create a User DSN, which will be unique only to the current user, click the [ADD...](#) button.
3. You will need to select the ODBC driver for this DSN.

Select [MySQL ODBC 3.51 Driver](#), then click [FINISH](#).

4. You now need to configure the specific fields for the DSN you are creating through the [Add Data Source Name](#) dialog.

In the **DATA SOURCE NAME** box, enter the name of the data source you want to access. It can be any valid name that you choose.

5. In the **DESCRIPTION** box, enter some text to help identify the connection.
6. In the **SERVER** field, enter the name of the MySQL server host that you want to access. By default, it is `localhost`.
7. In the **USER** field, enter the user name to use for this connection.
8. In the **PASSWORD** field, enter the corresponding password for this connection.
9. The **DATABASE** pop-up should automatically populate with the list of databases that the user has permissions to access.
10. Click OK to save the DSN.

A completed DSN configuration may look like this:

You can verify the connection using the parameters you have entered by clicking the TEST button. If the connection could be made successfully, you will be notified with a `Success; connection was made!` dialog.

If the connection failed, you can obtain more information on the test and why it may have failed by clicking the DIAGNOSTICS... button to show additional error messages.

You can configure a number of options for a specific DSN by using either the CONNECT OPTIONS or ADVANCED tabs in the DSN configuration dialog.

The three options you can configure are:

- **PORT** sets the TCP/IP port number to use when communicating with MySQL. Communication with MySQL uses port 3306 by default. If your server is configured to use a different TCP/IP port, you must specify that port number here.
- **SOCKET** sets the name or location of a specific socket or Windows pipe to use when communicating with MySQL.
- **INITIAL STATEMENT** defines an SQL statement that will be executed when the connection to MySQL is opened. You can use this to set MySQL options for your connection, such as disabling autocommit.
- **CHARACTER SET** is a pop-up list from which you can select the default character set to be used with this connection. The Character Set option was added in 3.5.17.

The **ADVANCED** tab enables you to configure Connector/ODBC connection parameters. Refer to [Section 29.1.4.2, “Connector/ODBC Connection Parameters”](#), for information about the meaning of these options.

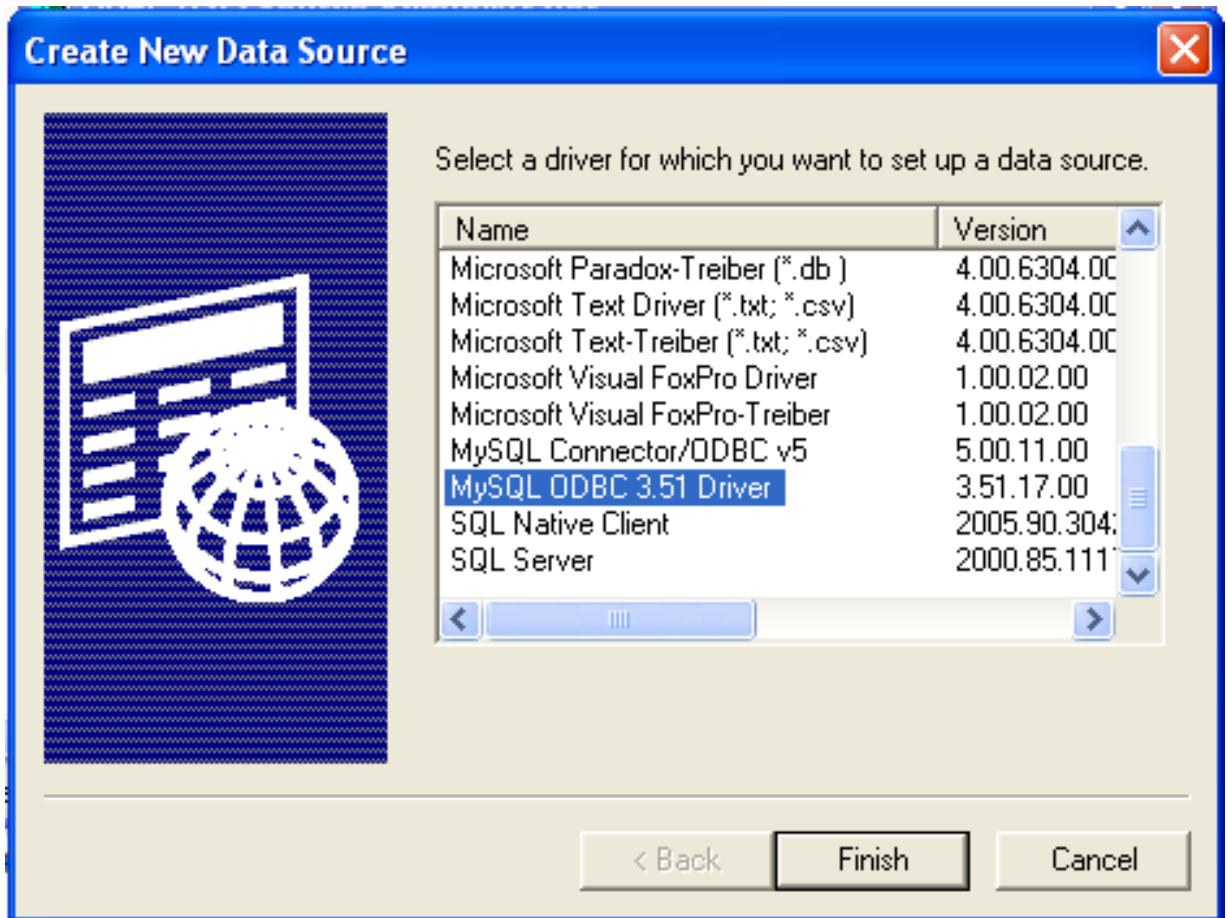

### 29.1.4.3.2. Configuring a Connector/ODBC 5.1 DSN on Windows

The DSN configuration when using Connector/ODBC 5.1.1 and later has a slightly different layout. Also, due to the native Unicode support within Connector/ODBC 5.1, you no longer need to specify the initial character set to be used with your connection.

To configure a DSN using the Connector/ODBC 5.1.1 or later driver:

1. Open the [ODBC Data Source Administrator](#).
2. To create a System DSN (which will be available to all users) , select the **SYSTEM DSN** tab. To create a User DSN, which will be unique only to the current user, click the **ADD...** button.
3. You will need to select the ODBC driver for this DSN.

Select [MySQL ODBC 3.51 Driver](#), then click FINISH.

4. You now need to configure the specific fields for the DSN you are creating through the [Connection Parameters](#) dialog.

MySQL Connector/ODBC Data Source Configuration

MySQL Connector/ODBC

Connection Parameters

Data Source Name:

Description:

Server:  Port:

User:

Password:

Database:

In the **DATA SOURCE NAME** box, enter the name of the data source you want to access. It can be any valid name that you choose.

5. In the **DESCRIPTION** box, enter some text to help identify the connection.
6. In the **SERVER** field, enter the name of the MySQL server host that you want to access. By default, it is `localhost`.
7. In the **USER** field, enter the user name to use for this connection.
8. In the **PASSWORD** field, enter the corresponding password for this connection.
9. The **DATABASE** pop-up should automatically populate with the list of databases that the user has permissions to access.
10. To communicate over a different TCP/IP port than the default (3306), change the value of the **PORT**.
11. Click OK to save the DSN.

You can verify the connection using the parameters you have entered by clicking the **TEST** button. If the connection could be made successfully, you will be notified with a `Success; connection was made!` dialog.

You can configure a number of options for a specific DSN by using the **DETAILS** button.

MySQL Connector/ODBC Data Source Configuration

MySQL Connector/ODBC

Connection Parameters

Data Source Name:

Description:

Server:  Port:

User:

Password:

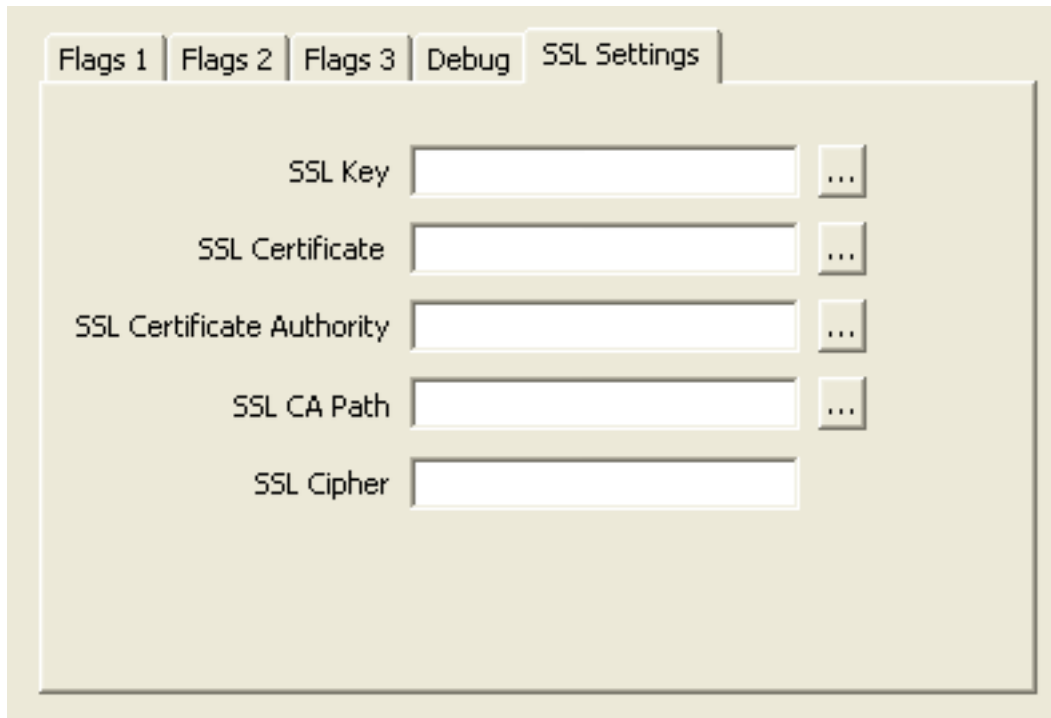

Database:

Flags 1 | Flags 2 | Flags 3 | Debug | SSL Settings

- Return matched rows instead of affected rows
- Allow big result sets
- Use compression
- Treat BIGINT columns as INT columns
- Enable safe options (see documentation)
- Enable automatic reconnect
- Enable SQL\_AUTO\_IS\_NULL

The **DETAILS** button opens a tabbed display which allows you to set additional options:

- **FLAGS 1**, **FLAGS 2**, and **FLAGS 3** enable you to select the additional flags for the DSN connection. For more information on these flags, see [Section 29.1.4.2, “Connector/ODBC Connection Parameters”](#).
- **DEBUG** allows you to enable ODBC debugging to record the queries you execute through the DSN to the `myodbc.sql` file. For more information, see [Section 29.1.4.8, “Getting an ODBC Trace File”](#).
- **SSL SETTINGS** configures the additional options required for using the Secure Sockets Layer (SSL) when communicating with MySQL server. Note that you must have enabled SSL and configured the MySQL server with suitable certificates to communicate over SSL.

The **ADVANCED** tab enables you to configure Connector/ODBC connection parameters. Refer to [Section 29.1.4.2, “Connector/ODBC Connection Parameters”](#), for information about the meaning of these options.

### 29.1.4.3.3. Errors and Debugging

This section answers Connector/ODBC connection-related questions.

- **While configuring a Connector/ODBC DSN, a [Could Not Load Translator or Setup Library](#) error occurs**

For more information, refer to [MS KnowledgeBase Article\(Q260558\)](#). Also, make sure you have the latest valid `ct13d32.dll` in your system directory.

- On Windows, the default `myodbc3.dll` is compiled for optimal performance. If you want to debug Connector/ODBC 3.51 (for example, to enable tracing), you should instead use `myodbc3d.dll`. To install this file, copy `myodbc3d.dll` over the installed `myodbc3.dll` file. Make sure to revert back to the release version of the driver DLL once you are done with the debugging because the debug version may cause performance issues. Note that the `myodbc3d.dll` isn't included in Connector/ODBC 3.51.07 through 3.51.11. If you are using one of these versions, you should copy that DLL from a previous version (for example, 3.51.06).

### 29.1.4.4. Configuring a Connector/ODBC DSN on Mac OS X

To configure a DSN on Mac OS X you can either use the `myodbc3i` utility, edit the `odbc.ini` file within the `Library/ODBC` directory of the user or the should use the ODBC Administrator. If you have Mac OS X 10.2 or earlier, refer to [Section 29.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#). Select whether you want to create a User DSN or a System DSN. If you want to add a System DSN, you may need to authenticate with the system. You must click the padlock and enter a user and password with administrator privileges.

For correct operation of ODBC Administrator, you should ensure that the `/Library/ODBC/odbc.ini` file used to set up ODBC connectivity and DSNs are writable by the `admin` group. If this file is not writable by this group then the ODBC Administrator may fail, or may appear to have worked but not generated the correct entry.

### Warning

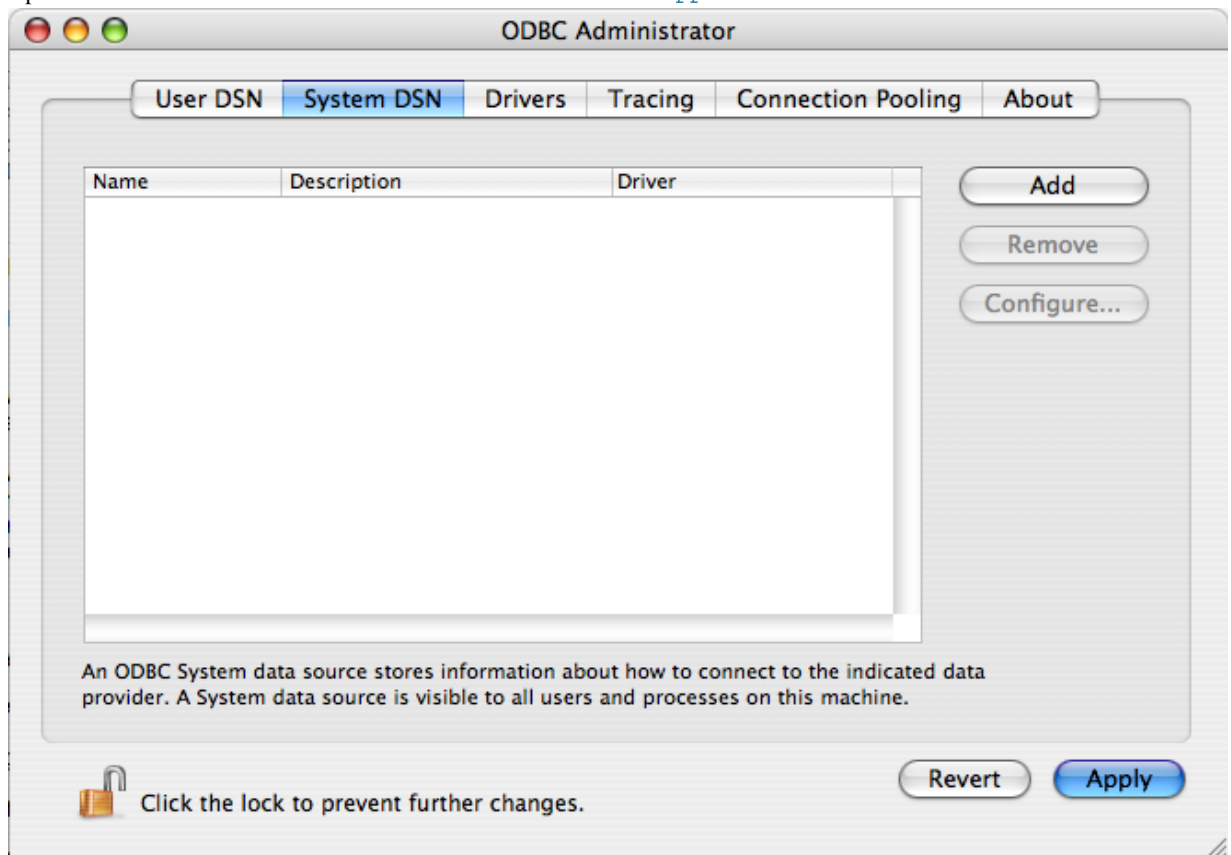

There are known issues with the OS X ODBC Administrator and Connector/ODBC that may prevent you from creating a DSN using this method. In this case you should use the command-line or edit the `odbc.ini` file directly. Note that existing DSNs or those that you create via the `myodbc3i` or `myodbc-installertool` can still be checked and edited using ODBC Administrator.

To create a DSN using the `myodbc3i` utility, you need only specify the DSN type and the DSN connection string. For example:

```
$ myodbc3i -a -s -t "DSN=mydb;DRIVER=MySQL ODBC 3.51 Driver;SERVER=mysql;USER=username;PASSWORD=pass"
```

To use ODBC Administrator:

1. Open the ODBC Administrator from the `Utilities` folder in the `Applications` folder.

2. On the User DSN or System DSN panel, click ADD.
3. Select the Connector/ODBC driver and click OK.
4. You will be presented with the `Data Source Name` dialog. Enter The `Data Source Name` and an optional `Description` for the DSN.

5. Click ADD to add a new keyword/value pair to the panel. You should configure at least four pairs to specify the `server`, `username`, `password` and `database` connection parameters. See [Section 29.1.4.2, “Connector/ODBC Connection Parameters”](#).
6. Click OK to add the DSN to the list of configured data source names.

A completed DSN configuration may look like this:

You can configure additional ODBC options to your DSN by adding further keyword/value pairs and setting the corresponding values. See [Section 29.1.4.2, “Connector/ODBC Connection Parameters”](#).

### 29.1.4.5. Configuring a Connector/ODBC DSN on Unix

On [Unix](#), you configure DSN entries directly in the `odbc.ini` file. Here is a typical `odbc.ini` file that configures `myodbc3` as the DSN name for Connector/ODBC 3.51:

```
;
; odbc.ini configuration for Connector/ODBC and Connector/ODBC 3.51 drivers
;

[ODBC Data Sources]
myodbc3 = MyODBC 3.51 Driver DSN

[myodbc3]
Driver = /usr/local/lib/libmyodbc3.so
Description = Connector/ODBC 3.51 Driver DSN
SERVER = localhost
PORT =
USER = root
Password =
Database = test
OPTION = 3
SOCKET =

[Default]
Driver = /usr/local/lib/libmyodbc3.so
Description = Connector/ODBC 3.51 Driver DSN
SERVER = localhost
PORT =
USER = root
Password =
Database = test
OPTION = 3
SOCKET =
```

Refer to the [Section 29.1.4.2, “Connector/ODBC Connection Parameters”](#), for the list of connection parameters that can be supplied.

#### Note

If you are using `unixODBC`, you can use the following tools to set up the DSN:

- ODBCConfig GUI tool([HOWTO: ODBCConfig](#))
- `odbcinst`

In some cases when using `unixODBC`, you might get this error:

```
Data source name not found and no default driver specified
```

If this happens, make sure the `ODBCINI` and `ODBCSYSINI` environment variables are pointing to the right `odbc.ini` file. For example, if your `odbc.ini` file is located in `/usr/local/etc`, set the environment variables like this:

```
export ODBCINI=/usr/local/etc/odbc.ini
export ODBCSYSINI=/usr/local/etc
```

### 29.1.4.6. Connecting Without a Predefined DSN

You can connect to the MySQL server using `SQLDriverConnect`, by specifying the `DRIVER` name field. Here are the connection strings for Connector/ODBC using DSN-Less connections:

#### For Connector/ODBC 3.51:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};\
SERVER=localhost;\
DATABASE=test;\
USER=venu;\
PASSWORD=venu;\
OPTION=3;"
```

If your programming language converts backslash followed by whitespace to a space, it is preferable to specify the connection string as a single long string, or to use a concatenation of multiple strings that does not add spaces in between. For example:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"
```

```
"SERVER=localhost;"
"DATABASE=test;"
"USER=venu;"
"PASSWORD=venu;"
"OPTION=3;"
```

**Note.** Note that on Mac OS X you may need to specify the full path to the Connector/ODBC driver library.

Refer to the [Section 29.1.4.2, “Connector/ODBC Connection Parameters”](#), for the list of connection parameters that can be supplied.

### 29.1.4.7. ODBC Connection Pooling

Connection pooling enables the ODBC driver to re-use existing connections to a given database from a pool of connections, instead of opening a new connection each time the database is accessed. By enabling connection pooling you can improve the overall performance of your application by lowering the time taken to open a connection to a database in the connection pool.

For more information about connection pooling: <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q169470>.

### 29.1.4.8. Getting an ODBC Trace File

If you encounter difficulties or problems with Connector/ODBC, you should start by making a log file from the [ODBC Manager](#) and Connector/ODBC. This is called *tracing*, and is enabled through the ODBC Manager. The procedure for this differs for Windows, Mac OS X and Unix.

#### 29.1.4.8.1. Enabling ODBC Tracing on Windows

To enable the trace option on Windows:

1. The [Tracing](#) tab of the ODBC Data Source Administrator dialog box enables you to configure the way ODBC function calls are traced.

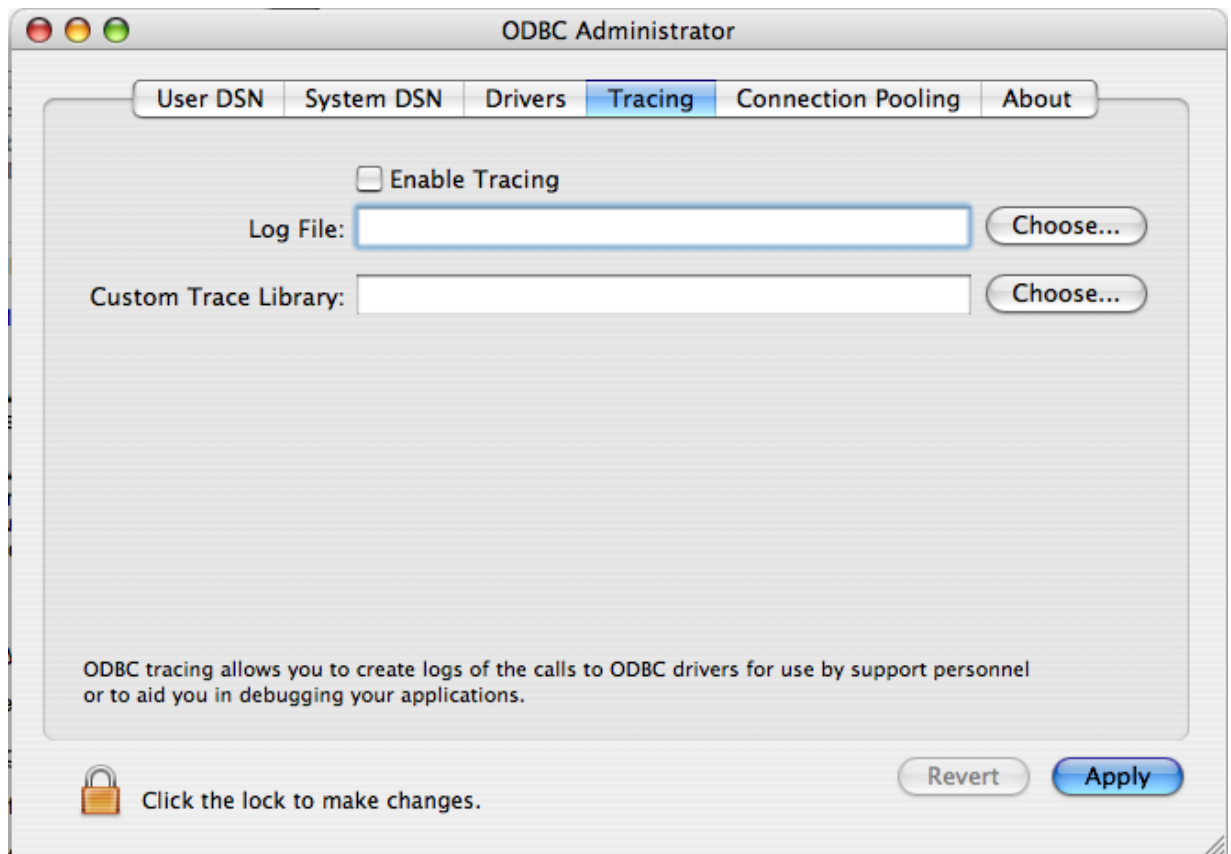

2. When you activate tracing from the [Tracing](#) tab, the [Driver Manager](#) logs all ODBC function calls for all subsequently run applications.
3. ODBC function calls from applications running before tracing is activated are not logged. ODBC function calls are recorded in a log file you specify.
4. Tracing ceases only after you click [Stop Tracing Now](#). Remember that while tracing is on, the log file continues to increase in size and that tracing affects the performance of all your ODBC applications.

#### 29.1.4.8.2. Enabling ODBC Tracing on Mac OS X

To enable the trace option on Mac OS X 10.3 or later you should use the [Tracing](#) tab within ODBC Administrator .

1. Open the ODBC Administrator.
2. Select the [Tracing](#) tab.

3. Select the `Enable Tracing` checkbox.
4. Enter the location where you want to save the Tracing log. If you want to append information to an existing log file, click the `CHOOSE...` button.

### 29.1.4.8.3. Enabling ODBC Tracing on Unix

To enable the trace option on Mac OS X 10.2 (or earlier) or Unix you must add the `trace` option to the ODBC configuration:

1. On Unix, you need to explicitly set the `Trace` option in the `ODBC.INI` file.

Set the tracing `ON` or `OFF` by using `TraceFile` and `Trace` parameters in `odbc.ini` as shown below:

```
TraceFile = /tmp/odbc.trace
Trace = 1
```

`TraceFile` specifies the name and full path of the trace file and `Trace` is set to `ON` or `OFF`. You can also use `1` or `YES` for `ON` and `0` or `NO` for `OFF`. If you are using `ODBCConfig` from `unixODBC`, then follow the instructions for tracing `unixODBC` calls at [HOWTO-ODBCConfig](#).

### 29.1.4.8.4. Enabling a Connector/ODBC Log

To generate a Connector/ODBC log, do the following:

1. Within Windows, enable the `Trace Connector/ODBC` option flag in the Connector/ODBC connect/configure screen. The log is written to file `C:\myodbc.log`. If the trace option is not remembered when you are going back to the above screen, it means that you are not using the `myodbcd.dll` driver, see [Section 29.1.4.3.3, "Errors and Debugging"](#).

On Mac OS X, Unix, or if you are using DSN-Less connection, then you need to supply `OPTION=4` in the connection string or set the corresponding keyword/value pair in the DSN.

2. Start your application and try to get it to fail. Then check the Connector/ODBC trace file to find out what could be wrong.

If you need help determining what is wrong, see [Section 29.1.8.1, “Connector/ODBC Community Support”](#).

## 29.1.5. Connector/ODBC Examples

Once you have configured a DSN to provide access to a database, how you access and use that connection is dependent on the application or programming language. As ODBC is a standardized interface, any application or language that supports ODBC can use the DSN and connect to the configured database.

### 29.1.5.1. Basic Connector/ODBC Application Steps

Interacting with a MySQL server from an applications using the Connector/ODBC typically involves the following operations:

- Configure the Connector/ODBC DSN
- Connect to MySQL server
- Initialization operations
- Execute SQL statements
- Retrieve results
- Perform Transactions
- Disconnect from the server

Most applications use some variation of these steps. The basic application steps are shown in the following diagram:

### 29.1.5.2. Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC

A typical installation situation where you would install Connector/ODBC is when you want to access a database on a Linux or Unix host from a Windows machine.

As an example of the process required to set up access between two machines, the steps below take you through the basic steps. These instructions assume that you want to connect to system ALPHA from system BETA with a username and password of `my-user` and `mypassword`.

On system ALPHA (the MySQL server) follow these steps:

1. Start the MySQL server.
2. Use `GRANT` to set up an account with a username of `myuser` that can connect from system BETA using a password of `myuser` to the database `test`:

```
GRANT ALL ON test.* to 'myuser'@'BETA' IDENTIFIED BY 'mypassword';
```

For more information about MySQL privileges, refer to [Section 5.5, “MySQL User Account Management”](#).

On system BETA (the Connector/ODBC client), follow these steps:

1. Configure a Connector/ODBC DSN using parameters that match the server, database and authentication information that you have just configured on system ALPHA.

| Parameter | Value       | Comment                                              |
|-----------|-------------|------------------------------------------------------|
| DSN       | remote_test | A name to identify the connection.                   |
| SERVER    | ALPHA       | The address of the remote server.                    |
| DATABASE  | test        | The name of the default database.                    |
| USER      | myuser      | The username configured for access to this database. |
| PASSWORD  | mypassword  | The password for <code>myuser</code> .               |

2. Using an ODBC-capable application, such as Microsoft Office, connect to the MySQL server using the DSN you have just created. If the connection fails, use tracing to examine the connection process. See [Section 29.1.4.8, “Getting an ODBC Trace File”](#), for more information.

### 29.1.5.3. Connector/ODBC and Third-Party ODBC Tools

Once you have configured your Connector/ODBC DSN, you can access your MySQL database through any application that supports the ODBC interface, including programming languages and third-party applications. This section contains guides and help on using Connector/ODBC with various ODBC-compatible tools and applications, including Microsoft Word, Microsoft Excel and Adobe/Macromedia ColdFusion.

Connector/ODBC has been tested with the following applications:

| Publisher           | Application                  | Notes                                                         |
|---------------------|------------------------------|---------------------------------------------------------------|
| Adobe               | ColdFusion                   | Formerly Macromedia ColdFusion                                |
| Borland             | C++ Builder                  |                                                               |
|                     | Builder 4                    |                                                               |
|                     | Delphi                       |                                                               |
| Business Objects    | Crystal Reports              |                                                               |
| Claris              | Filemaker Pro                |                                                               |
| Corel               | Paradox                      |                                                               |
| Computer Associates | Visual Objects               | Also known as CAVO                                            |
|                     | AllFusion ERwin Data Modeler |                                                               |
| Gupta               | Team Developer               | Previously known as Centura Team Developer; Gupta SQL/Windows |
| Gensym              | G2-ODBC Bridge               |                                                               |
| Inline              | iHTML                        |                                                               |
| Lotus               | Notes                        | Versions 4.5 and 4.6                                          |
| Microsoft           | Access                       |                                                               |
|                     | Excel                        |                                                               |
|                     | Visio Enterprise             |                                                               |
|                     | Visual C++                   |                                                               |
|                     | Visual Basic                 |                                                               |

|                     |                        |                             |
|---------------------|------------------------|-----------------------------|
|                     | ODBC.NET               | Using C#, Visual Basic, C++ |
|                     | FoxPro                 |                             |
|                     | Visual Interdev        |                             |
| OpenOffice.org      | OpenOffice.org         |                             |
| Perl                | DBD::ODBC              |                             |
| Pervasive Software  | DataJunction           |                             |
| Sambar Technologies | Sambar Server          |                             |
| SPSS                | SPSS                   |                             |
| SoftVelocity        | Clarion                |                             |
| SQLExpress          | SQLExpress for Xbase++ |                             |
| Sun                 | StarOffice             |                             |
| SunSystems          | Vision                 |                             |
| Sybase              | PowerBuilder           |                             |
|                     | PowerDesigner          |                             |
| theKompany.com      | Data Architect         |                             |

If you know of any other applications that work with Connector/ODBC, please send mail to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com) about them.

#### 29.1.5.4. Using Connector/ODBC with Microsoft Access

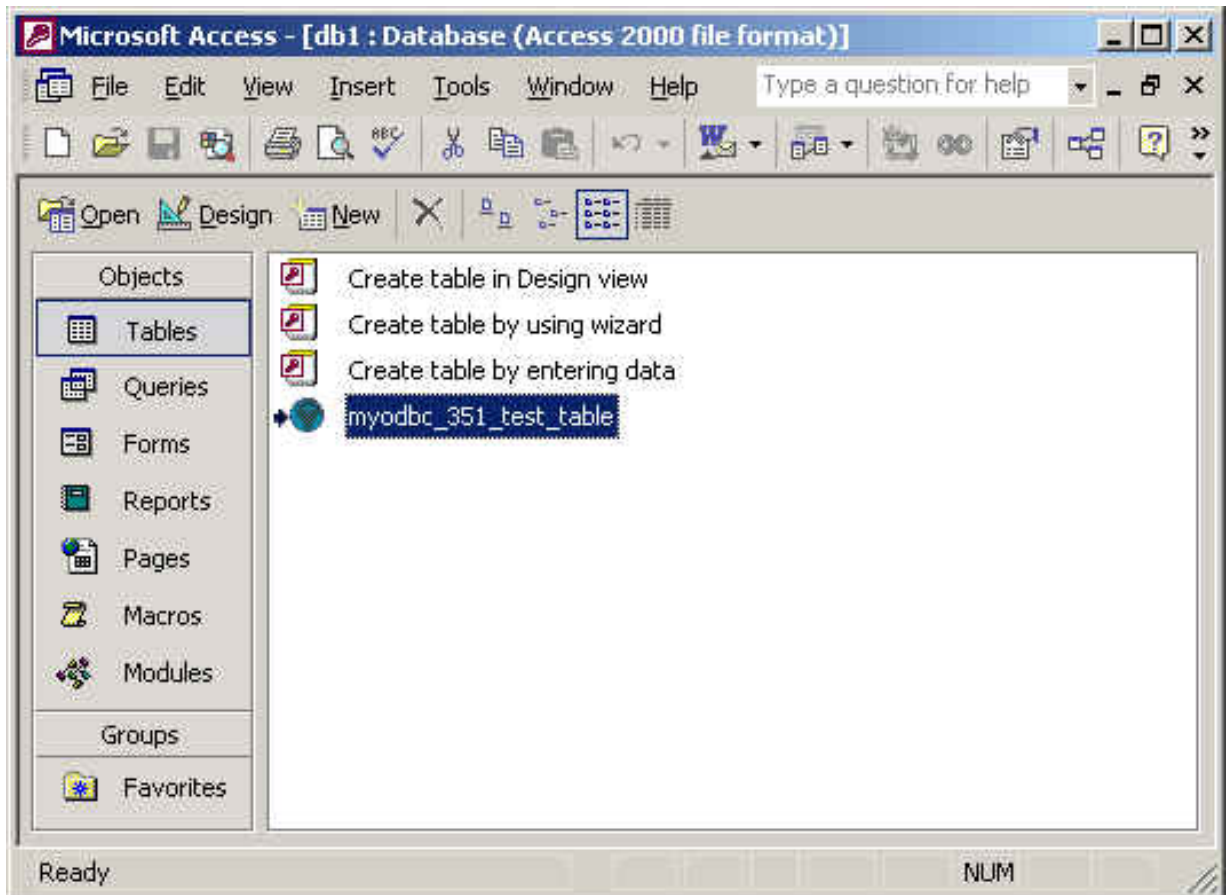

You can use MySQL database with Microsoft Access using Connector/ODBC. The MySQL database can be used as an import source, an export source, or as a linked table for direct use within an Access application, so you can use Access as the front-end interface to a MySQL database.

##### 29.1.5.4.1. Exporting Access Data to MySQL

To export a table of data from an Access database to MySQL, follow these instructions:

1. When you open an Access database or an Access project, a Database window appears. It displays shortcuts for creating new database objects and opening existing objects.

2. Click the name of the [table](#) or [query](#) you want to export, and then in the **File** menu, select **Export**.
3. In the **Export Object Type Object name To** dialog box, in the **Save As Type** box, select **ODBC Databases ()** as shown here:

4. In the **Export** dialog box, enter a name for the file (or use the suggested name), and then select **OK**.
5. The **Select Data Source** dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the **File Data Source** or **Machine Data Source** tab, and then double-click the **Connector/ODBC** or **Connector/ODBC 3.51** data source that you want to export to. To define a new data source for **Connector/ODBC**, please [Section 29.1.4.3, "Configuring a Connector/ODBC DSN on Windows"](#).

#### Note

Ensure that the information that you are exporting to the MySQL table is valid for the corresponding MySQL data types. Values that are outside of the supported range of the MySQL data type but valid within Access may trigger an "overflow" error during the export.

Microsoft Access connects to the MySQL Server through this data source and exports new tables and or data.

#### 29.1.5.4.2. Importing MySQL Data to Access

To import a table or tables from MySQL to Access, follow these instructions:

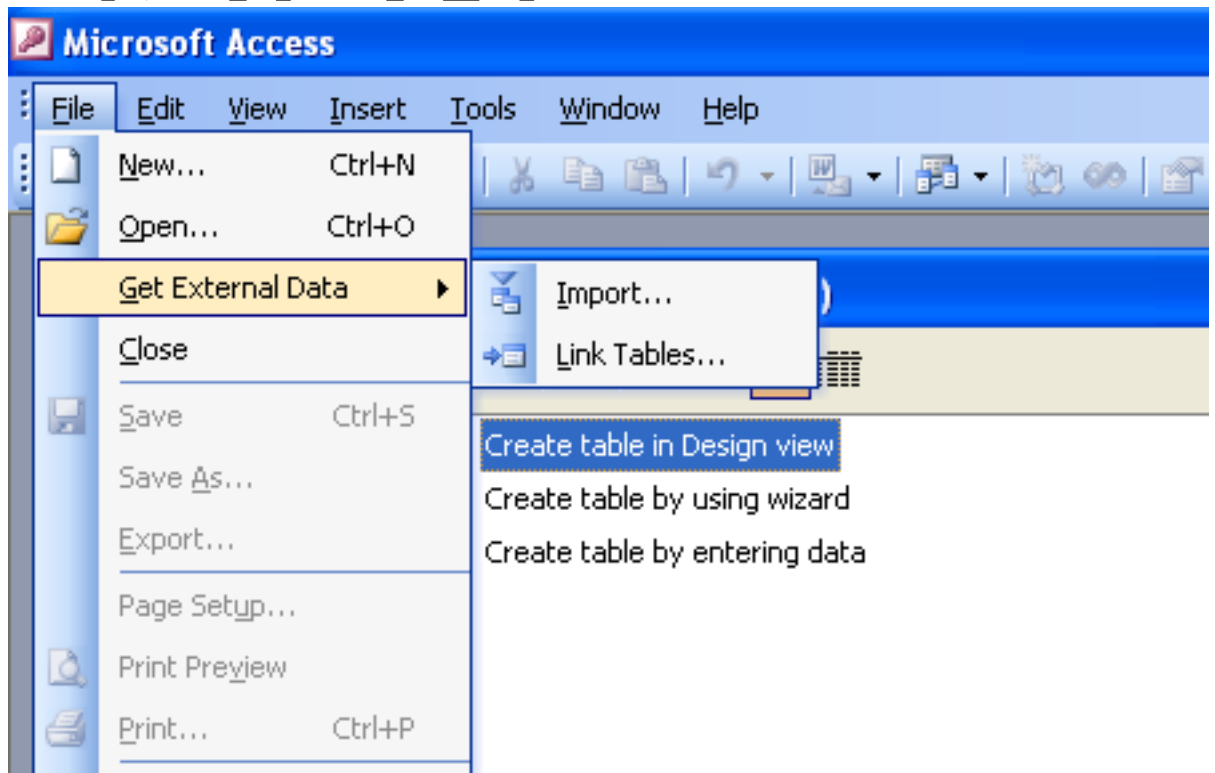

1. Open a database, or switch to the Database window for the open database.
2. To import tables, on the **File** menu, point to **Get External Data**, and then click **Import**.
3. In the **Import** dialog box, in the Files Of Type box, select **ODBC DATABASES ()**. The Select Data Source dialog box lists the defined data sources **THE SELECT DATA SOURCE** dialog box is displayed; it lists the defined data source names.
4. If the ODBC data source that you selected requires you to log on, enter your login ID and password (additional information might also be required), and then click **OK**.
5. Microsoft Access connects to the MySQL server through **ODBC data source** and displays the list of tables that you can **import**.
6. Click each table that you want to **import**, and then click **OK**.

### 29.1.5.4.3. Using Microsoft Access as a Front-end to MySQL

You can use Microsoft Access as a front end to a MySQL database by linking tables within your Microsoft Access database to tables that exist within your MySQL database. When a query is requested on a table within Access, ODBC is used to execute the queries on the MySQL database instead.

**To create a linked table:**

1. Open the Access database that you want to link to MySQL.
2. From the **FILE**, choose **GET EXTERNAL DATA->LINK TABLES**.

3. From the browser, choose **ODBC DATABASES ()** from the **FILES OF TYPE** pop-up.
4. In the **SELECT DATA SOURCE** window, choose an existing DSN, either from a **FILE DATA SOURCE** or **MACHINE DATA SOURCE**. You can also create a new DSN using the **NEW...** button. For more information on creating a DSN see [Section 29.1.4.3, "Configuring a Connector/ODBC DSN on Windows"](#).

5. In the **LINK TABLES** dialog, select one or more tables from the MySQL database. A link will be created to each table that you select from this list.

- If Microsoft Access is unable to determine the unique record identifier for a table automatically then it may ask you to confirm the column, or combination of columns, to be used to uniquely identify each row from the source table. Select the columns you want to use and click OK.

Once the process has been completed, you can now build interfaces and queries to the linked tables just as you would for any Access database.

Use the following procedure to view or to refresh links when the structure or location of a linked table has changed. The Linked Table Manager lists the paths to all currently linked tables.

**To view or refresh links:**

- Open the database that contains links to MySQL tables.
- On the **Tools** menu, point to **Add-ins (Database Utilities)** in Access 2000 or newer, and then click **Linked Table Manager**.
- Select the check box for the tables whose links you want to refresh.
- Click OK to refresh the links.

Microsoft Access confirms a successful refresh or, if the table wasn't found, displays the **Select New Location of <table name>** dialog box in which you can specify its the table's new location. If several selected tables have moved to the new location that you specify, the Linked Table Manager searches that location for all selected tables, and updates all links in one step.

**To change the path for a set of linked tables:**

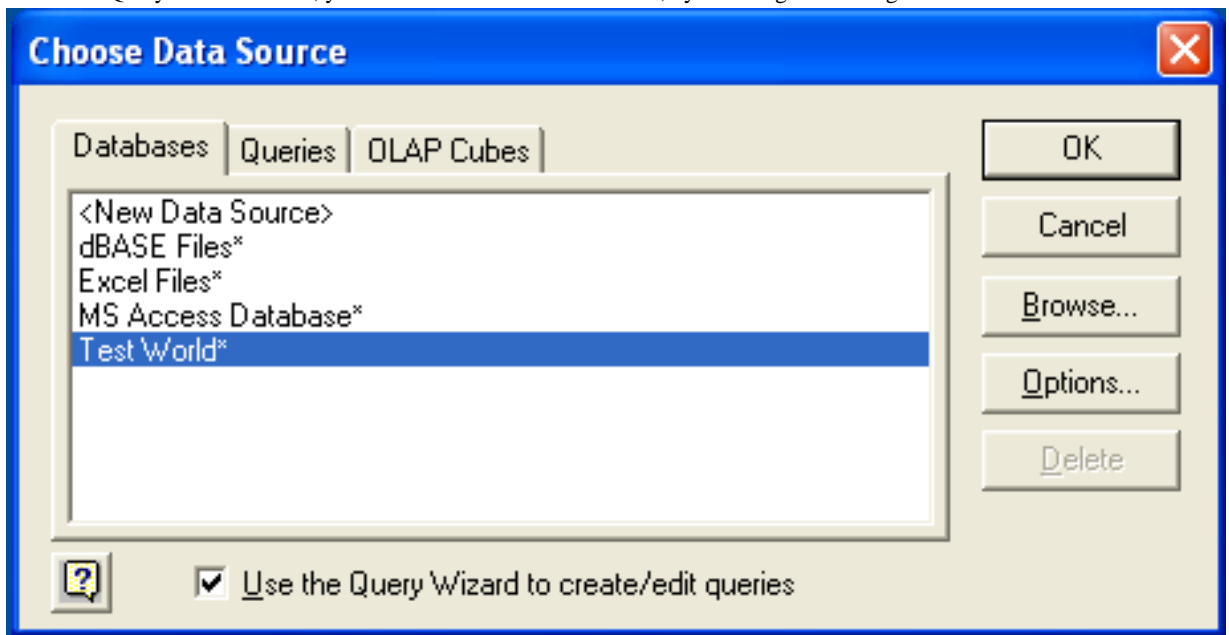

- Open the database that contains links to tables.
- On the **Tools** menu, point to **Add-ins (Database Utilities)** in Access 2000 or newer, and then click **Linked Table Manager**.
- Select the **Always Prompt For A New Location** check box.
- Select the check box for the tables whose links you want to change, and then click **OK**.
- In the **Select New Location of <table name>** dialog box, specify the new location, click **Open**, and then click **OK**.

### 29.1.5.5. Using Connector/ODBC with Microsoft Word or Excel

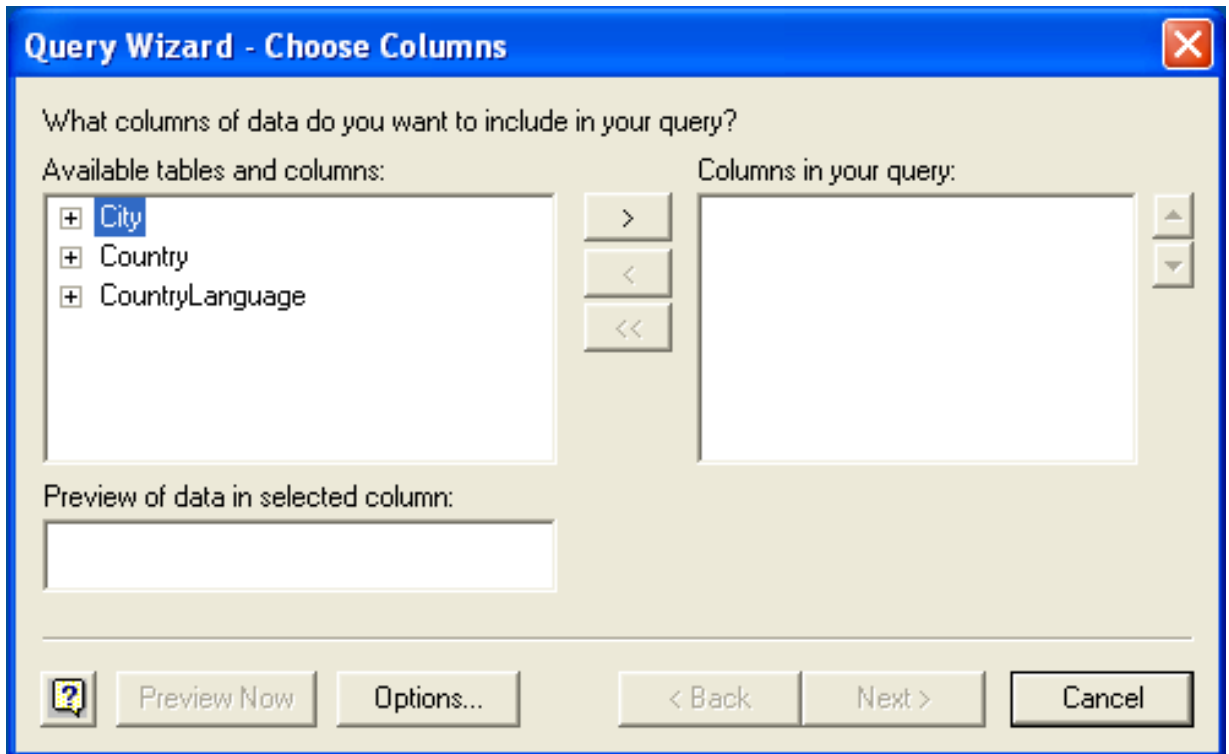

You can use Microsoft Word and Microsoft Excel to access information from a MySQL database using Connector/ODBC. Within Microsoft Word, this facility is most useful when importing data for mailmerge, or for tables and data to be included in reports. Within Microsoft Excel, you can execute queries on your MySQL server and import the data directly into an Excel Worksheet, presenting the data as a series of rows and columns.

With both applications, data is accessed and imported into the application using Microsoft Query, which enables you to execute a query through an ODBC source. You use Microsoft Query to build the SQL statement to be executed, selecting the tables, fields, selection criteria and sort order. For example, to insert information from a table in the World test database into an Excel spreadsheet, using the DSN samples shown in [Section 29.1.4, "Connector/ODBC Configuration"](#):

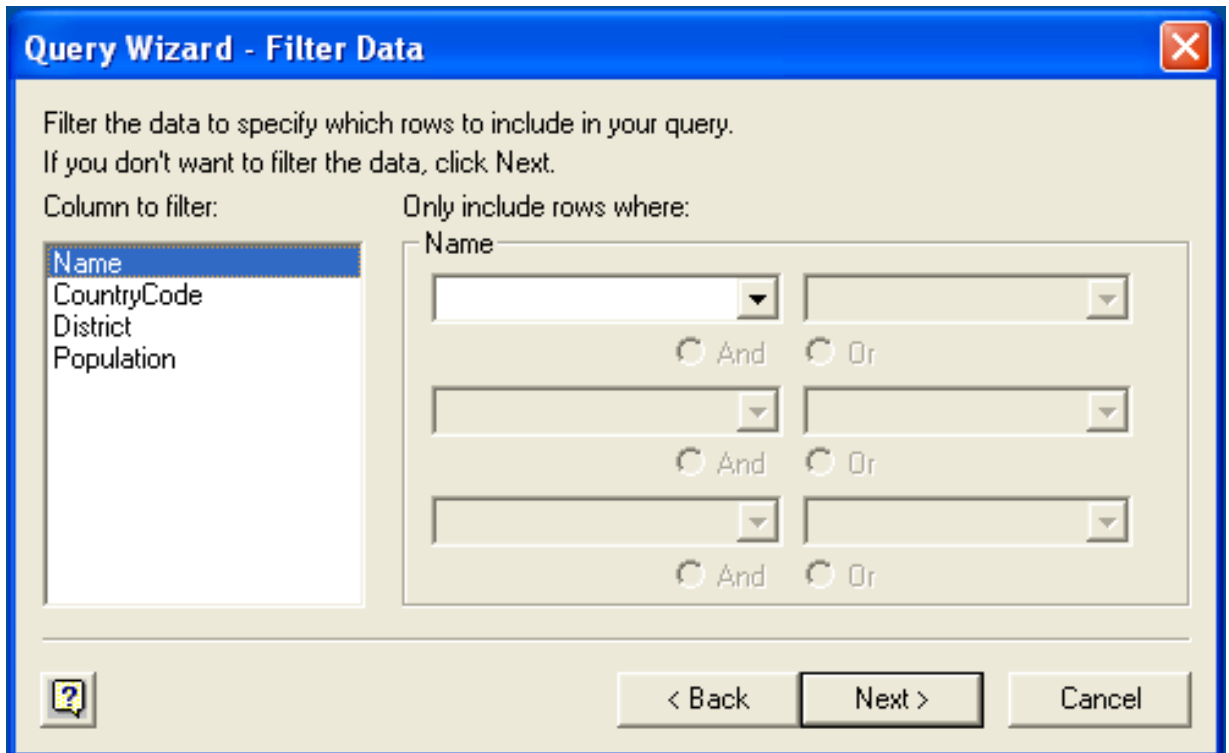

1. Create a new Worksheet.
2. From the **Data** menu, choose **Import External Data**, and then select **New Database Query**.
3. Microsoft Query will start. First, you need to choose the data source, by selecting an existing Data Source Name.

4. Within the **Query Wizard**, you must choose the columns that you want to import. The list of tables available to the user configured through the DSN is shown on the left, the columns that will be added to your query are shown on the right. The columns you choose are equivalent to those in the first section of a **SELECT** query. Click **NEXT** to continue.

5. You can filter rows from the query (the equivalent of a `WHERE` clause) using the `Filter Data` dialog. Click `NEXT` to continue.

6. Select an (optional) sort order for the data. This is equivalent to using a `ORDER BY` clause in your SQL query. You can select up to three fields for sorting the information returned by the query. Click `NEXT` to continue.

**Query Wizard - Sort Order**

Specify how you want your data sorted.  
If you don't want to sort the data, click Next.

Sort by  
Name  Ascending  Descending

Then by  Ascending  Descending

Then by  Ascending  Descending

< Back Next > Cancel

7. Select the destination for your query. You can select to return the data Microsoft Excel, where you can choose a worksheet and cell where the data will be inserted; you can continue to view the query and results within Microsoft Query, where you can edit the SQL query and further filter and sort the information returned; or you can create an OLAP Cube from the query, which can then be used directly within Microsoft Excel. Click FINISH.

**Query Wizard - Finish**

What would you like to do next?

Return Data to Microsoft Office Excel  View data or edit query in Microsoft Query  Create an OLAP Cube from this query

Save Query...

< Back Finish Cancel

The same process can be used to import data into a Word document, where the data will be inserted as a table. This can be used for mail merge purposes (where the field data is read from a Word table), or where you want to include data and reports within a report or other document.

### 29.1.5.6. Using Connector/ODBC with Crystal Reports

Crystal Reports can use an ODBC DSN to connect to a database from which you to extract data and information for reporting purposes.

**Note**

There is a known issue with certain versions of Crystal Reports where the application is unable to open and browse tables and fields through an ODBC connection. Before using Crystal Reports with MySQL, please ensure that you have update to the latest version, including any outstanding service packs and hotfixes. For more information on this issue, see the [Business\) Objects Knowledgebase](#) for more information.

For example, to create a simple crosstab report within Crystal Reports XI, you should follow these steps:

1. Create a DSN using the [Data Sources \(ODBC\)](#) tool. You can either specify a complete database, including username and password, or you can build a basic DSN and use Crystal Reports to set the username and password.

For the purposes of this example, a DSN that provides a connection to an instance of the MySQL Sakila sample database has been created.

2. Open Crystal Reports and create a new project, or an open an existing reporting project into which you want to insert data from your MySQL data source.
3. Start the Cross-Tab Report Wizard, either by clicking on the option on the Start Page. Expand the **CREATE NEW CONNECTION** folder, then expand the **ODBC (RDO)** folder to obtain a list of ODBC data sources.

You will be asked to select a data source.

4. When you first expand the **ODBC (RDO)** folder you will be presented the Data Source Selection screen. From here you can select either a pre-configured DSN, open a file-based DSN or enter and manual connection string. For this example, the **SAKILA** DSN will be used.

If the DSN contains a username/password combination, or you want to use different authentication credentials, click **NEXT** to enter the username and password that you want to use. Otherwise, click **FINISH** to continue the data source selection wizard.

5. You will be returned the Cross-Tab Report Creation Wizard. You now need to select the database and tables that you want to include in your report. For our example, we will expand the selected Sakila database. Click the `city` table and use the `>` button to add the table to the report. Then repeat the action with the `country` table. Alternatively you can select multiple tables and add them to the report.

Finally, you can select the parent **SAKILA** resource and add of the tables to the report.

Once you have selected the tables you want to include, click **NEXT** to continue.

6. Crystal Reports will now read the table definitions and automatically identify the links between the tables. The identification of links between tables enables Crystal Reports to automatically lookup and summarize information based on all the tables in the database according to your query. If Crystal Reports is unable to perform the linking itself, you can manually create the links between fields in the tables you have selected.

Click NEXT to continue the process.

7. You can now select the columns and rows that you wish to include within the Cross-Tab report. Drag and drop or use the > buttons to add fields to each area of the report. In the example shown, we will report on cities, organized by country, incorporating a count of the number of cities within each country. If you want to browse the data, select a field and click the BROWSE DATA... button.

Click NEXT to create a graph of the results. Since we are not creating a graph from this data, click FINISH to generate the report.

8. The finished report will be shown, a sample of the output from the Sakila sample database is shown below.

|                       |                       | <b>Total</b> |
|-----------------------|-----------------------|--------------|
| <b>Total</b>          |                       | 600          |
| <b>Afghanistan</b>    | <b>Total</b>          | 1            |
|                       | <b>Kabul</b>          | 1            |
| <b>Algeria</b>        | <b>Total</b>          | 3            |
|                       | <b>Batna</b>          | 1            |
|                       | <b>Bchar</b>          | 1            |
|                       | <b>Skikda</b>         | 1            |
| <b>American Samoa</b> | <b>Total</b>          | 1            |
|                       | <b>Tafuna</b>         | 1            |
| <b>Angola</b>         | <b>Total</b>          | 2            |
|                       | <b>Benguela</b>       | 1            |
|                       | <b>Namibe</b>         | 1            |
| <b>Anguilla</b>       | <b>Total</b>          | 1            |
|                       | <b>South Hill</b>     | 1            |
| <b>Argentina</b>      | <b>Total</b>          | 13           |
|                       | <b>Almirante Brow</b> | 1            |

Once the ODBC connection has been opened within Crystal Reports, you can browse and add any fields within the available tables into your reports.

### 29.1.5.7. Connector/ODBC Programming

With a suitable ODBC Manager and the Connector/ODBC driver installed, any programming language or environment that can support ODBC should be able to connect to a MySQL database through Connector/ODBC.

This includes, but is certainly not limited to, Microsoft support languages (including Visual Basic, C# and interfaces such as ODBC.NET), Perl (through the DBI module, and the DBD::ODBC driver).

#### 29.1.5.7.1. Using Connector/ODBC with Visual Basic Using ADO, DAO and RDO

This section contains simple examples of the use of MySQL ODBC 3.51 Driver with ADO, DAO and RDO.

### 29.1.5.7.1.1. ADO: `rs.addNew`, `rs.delete`, and `rs.update`

The following ADO (ActiveX Data Objects) example creates a table `my_ado` and demonstrates the use of `rs.addNew`, `rs.delete`, and `rs.update`.

```
Private Sub myodbc_ado_Click()

Dim conn As ADODB.Connection
Dim rs As ADODB.Recordset
Dim fld As ADODB.Field
Dim sql As String

'connect to MySQL server using MySQL ODBC 3.51 Driver
Set conn = New ADODB.Connection
conn.ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};" _
& "SERVER=localhost;" _
& "DATABASE=test;" _
& "UID=venu;PWD=venu; OPTION=3"

conn.Open

'create table
conn.Execute "DROP TABLE IF EXISTS my_ado"
conn.Execute "CREATE TABLE my_ado(id int not null primary key, name varchar(20)," _
& "txt text, dt date, tm time, ts timestamp)"

'direct insert
conn.Execute "INSERT INTO my_ado(id,name,txt) values(1,100,'venu')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(2,200,'MySQL')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(3,300,'Delete')"

Set rs = New ADODB.Recordset
rs.CursorLocation = adUseServer

'fetch the initial table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Initial my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close

'rs insert
rs.Open "select * from my_ado", conn, adOpenDynamic, adLockOptimistic
rs.AddNew
rs!Name = "Monty"
rs!txt = "Insert row"
rs.Update
rs.Close

'rs update
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-row"
rs.Update
rs.Close

'rs update second time..
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-second-time"
rs.Update
rs.Close

'rs delete
rs.Open "SELECT * FROM my_ado"
rs.MoveNext
rs.MoveNext
rs.Delete
rs.Close

'fetch the updated table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Updated my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
```

```

Next
rs.MoveNext
Debug.Print
Loop
rs.Close
conn.Close
End Sub

```

### 29.1.5.7.1.2. DAO: `rs.addNew`, `rs.update`, and Scrolling

The following DAO (Data Access Objects) example creates a table `my_dao` and demonstrates the use of `rs.addNew`, `rs.update`, and result set scrolling.

```

Private Sub myodbc_dao_Click()

Dim ws As Workspace
Dim conn As Connection
Dim queryDef As queryDef
Dim str As String

'connect to MySQL using MySQL ODBC 3.51 Driver
Set ws = DBEngine.CreateWorkspace("", "venu", "venu", dbUseODBC)
str = "odbc;DRIVER={MySQL ODBC 3.51 Driver};_"
& "SERVER=localhost;_"
& "DATABASE=test;_"
& "UID=venu;PWD=venu; OPTION=3"
Set conn = ws.OpenConnection("test", dbDriverNoPrompt, False, str)

'Create table my_dao
Set queryDef = conn.CreateQueryDef("", "drop table if exists my_dao")
queryDef.Execute

Set queryDef = conn.CreateQueryDef("", "create table my_dao(Id INT AUTO_INCREMENT PRIMARY KEY, " _
& "Ts TIMESTAMP(14) NOT NULL, Name varchar(20), Id2 INT)")
queryDef.Execute

'Insert new records using rs.addNew
Set rs = conn.OpenRecordset("my_dao")
Dim i As Integer

For i = 10 To 15
rs.AddNew
rs!Name = "insert record" & i
rs!Id2 = i
rs.Update
Next i
rs.Close

'rs update..
Set rs = conn.OpenRecordset("my_dao")
rs.Edit
rs!Name = "updated-string"
rs.Update
rs.Close

'fetch the table back...
Set rs = conn.OpenRecordset("my_dao", dbOpenDynamic)
str = "Results:"
rs.MoveFirst
While Not rs.EOF
str = " " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print "DATA:" & str
rs.MoveNext
Wend

'rs Scrolling
rs.MoveFirst
str = " FIRST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MoveLast
str = " LAST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MovePrevious
str = " LAST-1 ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

'free all resources
rs.Close
queryDef.Close
conn.Close
ws.Close

End Sub

```

### 29.1.5.7.1.3. RDO: `rs.addNew` and `rs.update`

The following RDO (Remote Data Objects) example creates a table `my_rdo` and demonstrates the use of `rs.addNew` and `rs.update`.

```

Dim rs As rdoResultset
Dim cn As New rdoConnection
Dim cl As rdoColumn
Dim SQL As String

'cn.Connect = "DSN=test;"
cn.Connect = "DRIVER={MySQL ODBC 3.51 Driver};" _
& "SERVER=localhost;" _
& "DATABASE=test;" _
& "UID=venu;PWD=venu; OPTION=3"

cn.CursorDriver = rdUseOdbc
cn.EstablishConnection rdDriverPrompt

'drop table my_rdo
SQL = "drop table if exists my_rdo"
cn.Execute SQL, rdExecDirect

'create table my_rdo
SQL = "create table my_rdo(id int, name varchar(20))"
cn.Execute SQL, rdExecDirect

'insert - direct
SQL = "insert into my_rdo values (100,'venu')"
cn.Execute SQL, rdExecDirect

SQL = "insert into my_rdo values (200,'MySQL')"
cn.Execute SQL, rdExecDirect

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 300
rs!Name = "Insert1"
rs.Update
rs.Close

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 400
rs!Name = "Insert 2"
rs.Update
rs.Close

'rs update
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.Edit
rs!id = 999
rs!Name = "updated"
rs.Update
rs.Close

'fetch back...
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
Do Until rs.EOF
For Each cl In rs.rdoColumns
Debug.Print cl.Value,
Next
rs.MoveNext
Debug.Print
Loop
Debug.Print "Row count="; rs.RowCount

'close
rs.Close
cn.Close

End Sub

```

### 29.1.5.7.2. Using Connector/ODBC with .NET

This section contains simple examples that demonstrate the use of Connector/ODBC drivers with ODBC.NET.

#### 29.1.5.7.2.1. Using Connector/ODBC with ODBC.NET and C# (C sharp)

The following sample creates a table `my_odbc_net` and demonstrates its use in C#.

```

/**
 * @sample : mycon.cs
 * @purpose : Demo sample for ODBC.NET using Connector/ODBC
 * @author : Venu, <myodbc@lists.mysql.com>
 *
 * (C) Copyright MySQL AB, 1995-2006
 *
 **/

```

```

/* build command
 *
 * csc /t:exe
 * /out:mycon.exe mycon.cs
 * /r:Microsoft.Data.Odbc.dll
 */

using Console = System.Console;
using Microsoft.Data.Odbc;

namespace myodbc3
{
 class mycon
 {
 static void Main(string[] args)
 {
 try
 {
 //Connection string for Connector/ODBC 3.51
 string MyConString = "DRIVER={MySQL ODBC 3.51 Driver};" +
 "SERVER=localhost;" +
 "DATABASE=test;" +
 "UID=venu;" +
 "PASSWORD=venu;" +
 "OPTION=3";

 //Connect to MySQL using Connector/ODBC
 OdbcConnection MyConnection = new OdbcConnection(MyConString);
 MyConnection.Open();

 Console.WriteLine("\n !!! success, connected successfully !!!\n");

 //Display connection information
 Console.WriteLine("Connection Information:");
 Console.WriteLine("\tConnection String:" +
 MyConnection.ConnectionString);
 Console.WriteLine("\tConnection Timeout:" +
 MyConnection.ConnectionTimeout);
 Console.WriteLine("\tDatabase:" +
 MyConnection.Database);
 Console.WriteLine("\tDataSource:" +
 MyConnection.DataSource);
 Console.WriteLine("\tDriver:" +
 MyConnection.Driver);
 Console.WriteLine("\tServerVersion:" +
 MyConnection.ServerVersion);

 //Create a sample table
 OdbcCommand MyCommand =
 new OdbcCommand("DROP TABLE IF EXISTS my_odbc_net",
 MyConnection);
 MyCommand.ExecuteNonQuery();
 MyCommand.CommandText =
 "CREATE TABLE my_odbc_net(id int, name varchar(20), idb bigint)";
 MyCommand.ExecuteNonQuery();

 //Insert
 MyCommand.CommandText =
 "INSERT INTO my_odbc_net VALUES(10,'venu', 300)";
 Console.WriteLine("INSERT, Total rows affected:" +
 MyCommand.ExecuteNonQuery());

 //Insert
 MyCommand.CommandText =
 "INSERT INTO my_odbc_net VALUES(20,'mysql',400)";
 Console.WriteLine("INSERT, Total rows affected:" +
 MyCommand.ExecuteNonQuery());

 //Insert
 MyCommand.CommandText =
 "INSERT INTO my_odbc_net VALUES(20,'mysql',500)";
 Console.WriteLine("INSERT, Total rows affected:" +
 MyCommand.ExecuteNonQuery());

 //Update
 MyCommand.CommandText =
 "UPDATE my_odbc_net SET id=999 WHERE id=20";
 Console.WriteLine("Update, Total rows affected:" +
 MyCommand.ExecuteNonQuery());

 //COUNT(*)
 MyCommand.CommandText =
 "SELECT COUNT(*) as TRows FROM my_odbc_net";
 Console.WriteLine("Total Rows:" +
 MyCommand.ExecuteScalar());

 //Fetch
 MyCommand.CommandText = "SELECT * FROM my_odbc_net";
 OdbcDataReader MyDataReader;
 MyDataReader = MyCommand.ExecuteReader();
 while (MyDataReader.Read())
 {
 if(string.Compare(MyConnection.Driver,"myodbc3.dll") == 0) {
 //Supported only by Connector/ODBC 3.51
 Console.WriteLine("Data:" + MyDataReader.GetInt32(0) + " " +
 MyDataReader.GetString(1) + " " +
 MyDataReader.GetInt64(2));
 }
 }
 }
 }
 }
}

```

```

 else {
 //BIGINTs not supported by Connector/ODBC
 Console.WriteLine("Data:" + MyDataReader.GetInt32(0) + " " +
 MyDataReader.GetString(1) + " " +
 MyDataReader.GetInt32(2));
 }
 }

 //Close all resources
 MyDataReader.Close();
 MyConnection.Close();
}
catch (OdbcException MyOdbcException) //Catch any ODBC exception ..
{
 for (int i=0; i < MyOdbcException.Errors.Count; i++)
 {
 Console.WriteLine("ERROR #" + i + "\n" +
 "Message: " +
 MyOdbcException.Errors[i].Message + "\n" +
 "Native: " +
 MyOdbcException.Errors[i].NativeError.ToString() + "\n" +
 "Source: " +
 MyOdbcException.Errors[i].Source + "\n" +
 "SQL: " +
 MyOdbcException.Errors[i].SQLState + "\n");
 }
}
}
}
}
}

```

### 29.1.5.7.2.2. Using Connector/ODBC with ODBC.NET and Visual Basic

The following sample creates a table `my_vb_net` and demonstrates the use in VB.

```

' @sample : myvb.vb
' @purpose : Demo sample for ODBC.NET using Connector/ODBC
' @author : Venu, <myodbc@lists.mysql.com>
'
' (C) Copyright MySQL AB, 1995-2006
'
'
'
' build command
'
' vbc /target:exe
' /out:myvb.exe
' /r:Microsoft.Data.Odbc.dll
' /r:System.dll
' /r:System.Data.dll
'
Imports Microsoft.Data.Odbc
Imports System

Module myvb
 Sub Main()
 Try

 'Connector/ODBC 3.51 connection string
 Dim MyConString As String = "DRIVER={MySQL ODBC 3.51 Driver};" & _
 "SERVER=localhost;" & _
 "DATABASE=test;" & _
 "UID=venu;" & _
 "PASSWORD=venu;" & _
 "OPTION=3;"

 'Connection
 Dim MyConnection As New OdbcConnection(MyConString)
 MyConnection.Open()

 Console.WriteLine("Connection State::" & MyConnection.State.ToString)

 'Drop
 Console.WriteLine("Dropping table")
 Dim MyCommand As New OdbcCommand()
 MyCommand.Connection = MyConnection
 MyCommand.CommandText = "DROP TABLE IF EXISTS my_vb_net"
 MyCommand.ExecuteNonQuery()

 'Create
 Console.WriteLine("Creating...")
 MyCommand.CommandText = "CREATE TABLE my_vb_net(id int, name varchar(30))"
 MyCommand.ExecuteNonQuery()

 'Insert
 MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(10,'venu')"
 Console.WriteLine("INSERT, Total rows affected:" & _
 MyCommand.ExecuteNonQuery())

 'Insert
 MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(20,'mysql')"
 Console.WriteLine("INSERT, Total rows affected:" & _
 MyCommand.ExecuteNonQuery())
 }
 }
}

```

```

'Insert
MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(20,'mysql')"
Console.WriteLine("INSERT, Total rows affected:" & _
MyCommand.ExecuteNonQuery())

'Insert
MyCommand.CommandText = "INSERT INTO my_vb_net(id) VALUES(30)"
Console.WriteLine("INSERT, Total rows affected:" & _
MyCommand.ExecuteNonQuery())

'Update
MyCommand.CommandText = "UPDATE my_vb_net SET id=999 WHERE id=20"
Console.WriteLine("Update, Total rows affected:" & _
MyCommand.ExecuteNonQuery())

'COUNT(*)
MyCommand.CommandText = "SELECT COUNT(*) as TRows FROM my_vb_net"
Console.WriteLine("Total Rows:" & MyCommand.ExecuteScalar())

'Select
Console.WriteLine("Select * FROM my_vb_net")
MyCommand.CommandText = "SELECT * FROM my_vb_net"
Dim MyDataReader As OdbcDataReader
MyDataReader = MyCommand.ExecuteReader
While MyDataReader.Read
If MyDataReader("name") Is DBNull.Value Then
Console.WriteLine("id = " & _
CStr(MyDataReader("id")) & " name = " & _
"NULL")
Else
Console.WriteLine("id = " & _
CStr(MyDataReader("id")) & " name = " & _
CStr(MyDataReader("name")))
End If
End While

'Catch ODBC Exception
Catch MyOdbcException As OdbcException
Dim i As Integer
Console.WriteLine(MyOdbcException.ToString)

'Catch program exception
Catch MyException As Exception
Console.WriteLine(MyException.ToString)
End Try
End Sub

```

## 29.1.6. Connector/ODBC Reference

This section provides reference material for the Connector/ODBC API, showing supported functions and methods, supported MySQL column types and the corresponding native type in Connector/ODBC, and the error codes returned by Connector/ODBC when a fault occurs.

### 29.1.6.1. Connector/ODBC API Reference

This section summarizes ODBC routines, categorized by functionality.

For the complete ODBC API reference, please refer to the ODBC Programmer's Reference at <http://msdn.microsoft.com/en-us/library/ms714177.aspx>.

An application can call [SQLGetInfo](#) function to obtain conformance information about Connector/ODBC. To obtain information about support for a specific function in the driver, an application can call [SQLGetFunctions](#).

#### Note

For backward compatibility, the Connector/ODBC 3.51 driver supports all deprecated functions.

The following tables list Connector/ODBC API calls grouped by task:

#### Connecting to a data source:

| Function name                    | C/ODBC 3.51 | Standard | Purpose                                                                                                                                         |
|----------------------------------|-------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SQLAllocHandle</a>   | Yes         | ISO 92   | Obtains an environment, connection, statement, or descriptor handle.                                                                            |
| <a href="#">SQLConnect</a>       | Yes         | ISO 92   | Connects to a specific driver by data source name, user ID, and password.                                                                       |
| <a href="#">SQLDriverConnect</a> | Yes         | ODBC     | Connects to a specific driver by connection string or requests that the Driver Manager and driver display connection dialog boxes for the user. |

|                                 |     |            |                                                      |
|---------------------------------|-----|------------|------------------------------------------------------|
| <a href="#">SQLAllocEnv</a>     | Yes | Deprecated | Obtains an environment handle allocated from driver. |
| <a href="#">SQLAllocConnect</a> | Yes | Deprecated | Obtains a connection handle                          |

**Obtaining information about a driver and data source:**

| Function name                   | C/ODBC 3.51 | Standard | Purpose                                                                               |
|---------------------------------|-------------|----------|---------------------------------------------------------------------------------------|
| <a href="#">SQLDataSources</a>  | No          | ISO 92   | Returns the list of available data sources, handled by the Driver Manager             |
| <a href="#">SQLDrivers</a>      | No          | ODBC     | Returns the list of installed drivers and their attributes, handles by Driver Manager |
| <a href="#">SQLGetInfo</a>      | Yes         | ISO 92   | Returns information about a specific driver and data source.                          |
| <a href="#">SQLGetFunctions</a> | Yes         | ISO 92   | Returns supported driver functions.                                                   |
| <a href="#">SQLGetTypeInfo</a>  | Yes         | ISO 92   | Returns information about supported data types.                                       |

**Setting and retrieving driver attributes:**

| Function name                       | C/ODBC 3.51 | Standard   | Purpose                                        |
|-------------------------------------|-------------|------------|------------------------------------------------|
| <a href="#">SQLSetConnectAttr</a>   | Yes         | ISO 92     | Sets a connection attribute.                   |
| <a href="#">SQLGetConnectAttr</a>   | Yes         | ISO 92     | Returns the value of a connection attribute.   |
| <a href="#">SQLSetConnectOption</a> | Yes         | Deprecated | Sets a connection option                       |
| <a href="#">SQLGetConnectOption</a> | Yes         | Deprecated | Returns the value of a connection option       |
| <a href="#">SQLSetEnvAttr</a>       | Yes         | ISO 92     | Sets an environment attribute.                 |
| <a href="#">SQLGetEnvAttr</a>       | Yes         | ISO 92     | Returns the value of an environment attribute. |
| <a href="#">SQLSetStmtAttr</a>      | Yes         | ISO 92     | Sets a statement attribute.                    |
| <a href="#">SQLGetStmtAttr</a>      | Yes         | ISO 92     | Returns the value of a statement attribute.    |
| <a href="#">SQLSetStmtOption</a>    | Yes         | Deprecated | Sets a statement option                        |
| <a href="#">SQLGetStmtOption</a>    | Yes         | Deprecated | Returns the value of a statement option        |

**Preparing SQL requests:**

| Function name                       | C/ODBC 3.51 | Standard   | Purpose                                                     |
|-------------------------------------|-------------|------------|-------------------------------------------------------------|
| <a href="#">SQLAllocStmt</a>        | Yes         | Deprecated | Allocates a statement handle                                |
| <a href="#">SQLPrepare</a>          | Yes         | ISO 92     | Prepares an SQL statement for later execution.              |
| <a href="#">SQLBindParameter</a>    | Yes         | ODBC       | Assigns storage for a parameter in an SQL statement.        |
| <a href="#">SQLGetCursorName</a>    | Yes         | ISO 92     | Returns the cursor name associated with a statement handle. |
| <a href="#">SQLSetCursorName</a>    | Yes         | ISO 92     | Specifies a cursor name.                                    |
| <a href="#">SQLSetScrollOptions</a> | Yes         | ODBC       | Sets options that control cursor behavior.                  |

**Submitting requests:**

| Function name                    | C/ODBC 3.51 | Standard | Purpose                                                                                                                        |
|----------------------------------|-------------|----------|--------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SQLExecute</a>       | Yes         | ISO 92   | Executes a prepared statement.                                                                                                 |
| <a href="#">SQLExecDirect</a>    | Yes         | ISO 92   | Executes a statement                                                                                                           |
| <a href="#">SQLNativeSql</a>     | Yes         | ODBC     | Returns the text of an SQL statement as translated by the driver.                                                              |
| <a href="#">SQLDescribeParam</a> | Yes         | ODBC     | Returns the description for a specific parameter in a statement.                                                               |
| <a href="#">SQLNumParams</a>     | Yes         | ISO 92   | Returns the number of parameters in a statement.                                                                               |
| <a href="#">SQLParamData</a>     | Yes         | ISO 92   | Used in conjunction with <a href="#">SQLPutData</a> to supply parameter data at execution time. (Useful for long data values.) |

|            |     |        |                                                                                   |
|------------|-----|--------|-----------------------------------------------------------------------------------|
| SQLPutData | Yes | ISO 92 | Sends part or all of a data value for a parameter. (Useful for long data values.) |
|------------|-----|--------|-----------------------------------------------------------------------------------|

**Retrieving results and information about results:**

| Function name     | C/ODBC 3.51 | Standard   | Purpose                                                                                                                                                  |
|-------------------|-------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQLRowCount       | Yes         | ISO 92     | Returns the number of rows affected by an insert, update, or delete request.                                                                             |
| SQLNumResultCols  | Yes         | ISO 92     | Returns the number of columns in the result set.                                                                                                         |
| SQLDescribeCol    | Yes         | ISO 92     | Describes a column in the result set.                                                                                                                    |
| SQLColAttribute   | Yes         | ISO 92     | Describes attributes of a column in the result set.                                                                                                      |
| SQLColAttributes  | Yes         | Deprecated | Describes attributes of a column in the result set.                                                                                                      |
| SQLFetch          | Yes         | ISO 92     | Returns multiple result rows.                                                                                                                            |
| SQLFetchScroll    | Yes         | ISO 92     | Returns scrollable result rows.                                                                                                                          |
| SQLExtendedFetch  | Yes         | Deprecated | Returns scrollable result rows.                                                                                                                          |
| SQLSetPos         | Yes         | ODBC       | Positions a cursor within a fetched block of data and allows an application to refresh data in the rowset or to update or delete data in the result set. |
| SQLBulkOperations | Yes         | ODBC       | Performs bulk insertions and bulk bookmark operations, including update, delete, and fetch by bookmark.                                                  |

**Retrieving error or diagnostic information:**

| Function name   | C/ODBC 3.51 | Standard   | Purpose                                                                                       |
|-----------------|-------------|------------|-----------------------------------------------------------------------------------------------|
| SQLError        | Yes         | Deprecated | Returns additional error or status information                                                |
| SQLGetDiagField | Yes         | ISO 92     | Returns additional diagnostic information (a single field of the diagnostic data structure).  |
| SQLGetDiagRec   | Yes         | ISO 92     | Returns additional diagnostic information (multiple fields of the diagnostic data structure). |

**Obtaining information about the data source's system tables (catalog functions) item:**

| Function name       | C/ODBC 3.51 | Standard | Purpose                                                                                                                                                                                                        |
|---------------------|-------------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQLColumnPrivileges | Yes         | ODBC     | Returns a list of columns and associated privileges for one or more tables.                                                                                                                                    |
| SQLColumns          | Yes         | X/Open   | Returns the list of column names in specified tables.                                                                                                                                                          |
| SQLForeignKeys      | Yes         | ODBC     | Returns a list of column names that make up foreign keys, if they exist for a specified table.                                                                                                                 |
| SQLPrimaryKeys      | Yes         | ODBC     | Returns the list of column names that make up the primary key for a table.                                                                                                                                     |
| SQLSpecialColumns   | Yes         | X/Open   | Returns information about the optimal set of columns that uniquely identifies a row in a specified table, or the columns that are automatically updated when any value in the row is updated by a transaction. |
| SQLStatistics       | Yes         | ISO 92   | Returns statistics about a single table and the list of indexes associated with the table.                                                                                                                     |
| SQLTablePrivileges  | Yes         | ODBC     | Returns a list of tables and the privileges associated with each table.                                                                                                                                        |
| SQLTables           | Yes         | X/Open   | Returns the list of table names stored in a specific data source.                                                                                                                                              |

**Performing transactions:**

| Function name               | C/ODBC 3.51 | Standard   | Purpose                              |
|-----------------------------|-------------|------------|--------------------------------------|
| <a href="#">SQLTransact</a> | Yes         | Deprecated | Commits or rolls back a transaction  |
| <a href="#">SQLEndTran</a>  | Yes         | ISO 92     | Commits or rolls back a transaction. |

**Terminating a statement:**

| Function name                  | C/ODBC 3.51 | Standard | Purpose                                                                                                                         |
|--------------------------------|-------------|----------|---------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SQLFreeStmt</a>    | Yes         | ISO 92   | Ends statement processing, discards pending results, and, optionally, frees all resources associated with the statement handle. |
| <a href="#">SQLCloseCursor</a> | Yes         | ISO 92   | Closes a cursor that has been opened on a statement handle.                                                                     |
| <a href="#">SQLCancel</a>      | Yes         | ISO 92   | Cancels an SQL statement.                                                                                                       |

**Terminating a connection:**

| Function name                  | C/ODBC 3.51 | Standard   | Purpose                                                               |
|--------------------------------|-------------|------------|-----------------------------------------------------------------------|
| <a href="#">SQLDisconnect</a>  | Yes         | ISO 92     | Closes the connection.                                                |
| <a href="#">SQLFreeHandle</a>  | Yes         | ISO 92     | Releases an environment, connection, statement, or descriptor handle. |
| <a href="#">SQLFreeConnect</a> | Yes         | Deprecated | Releases connection handle                                            |
| <a href="#">SQLFreeEnv</a>     | Yes         | Deprecated | Releases an environment handle                                        |

**29.1.6.2. Connector/ODBC Data Types**

The following table illustrates how driver maps the server data types to default SQL and C data types:

| Native Value                     | SQL Type          | C Type          |
|----------------------------------|-------------------|-----------------|
| <a href="#">bigint unsigned</a>  | SQL_BIGINT        | SQL_C_UBIGINT   |
| <a href="#">bigint</a>           | SQL_BIGINT        | SQL_C_SBIGINT   |
| <a href="#">bit</a>              | SQL_BIT           | SQL_C_BIT       |
| <a href="#">bit</a>              | SQL_CHAR          | SQL_C_CHAR      |
| <a href="#">blob</a>             | SQL_LONGVARBINARY | SQL_C_BINARY    |
| <a href="#">bool</a>             | SQL_CHAR          | SQL_C_CHAR      |
| <a href="#">char</a>             | SQL_CHAR          | SQL_C_CHAR      |
| <a href="#">date</a>             | SQL_DATE          | SQL_C_DATE      |
| <a href="#">datetime</a>         | SQL_TIMESTAMP     | SQL_C_TIMESTAMP |
| <a href="#">decimal</a>          | SQL_DECIMAL       | SQL_C_CHAR      |
| <a href="#">double precision</a> | SQL_DOUBLE        | SQL_C_DOUBLE    |
| <a href="#">double</a>           | SQL_FLOAT         | SQL_C_DOUBLE    |
| <a href="#">enum</a>             | SQL_VARCHAR       | SQL_C_CHAR      |
| <a href="#">float</a>            | SQL_REAL          | SQL_C_FLOAT     |
| <a href="#">int unsigned</a>     | SQL_INTEGER       | SQL_C_ULONG     |
| <a href="#">int</a>              | SQL_INTEGER       | SQL_C_SLONG     |
| <a href="#">integer unsigned</a> | SQL_INTEGER       | SQL_C_ULONG     |
| <a href="#">integer</a>          | SQL_INTEGER       | SQL_C_SLONG     |
| <a href="#">long varbinary</a>   | SQL_LONGVARBINARY | SQL_C_BINARY    |
| <a href="#">long varchar</a>     | SQL_LONGVARCHAR   | SQL_C_CHAR      |

| year               | SQL_SMALLINT      | SQL_C_SHORT     |

### 29.1.6.3. Connector/ODBC Error Codes

The following tables lists the error codes returned by the driver apart from the server errors.

| Native Code | SQLSTATE 2 | SQLSTATE 3 | Error Message                                                     |
|-------------|------------|------------|-------------------------------------------------------------------|
| 500         | 01000      | 01000      | General warning                                                   |
| 501         | 01004      | 01004      | String data, right truncated                                      |
| 502         | 01S02      | 01S02      | Option value changed                                              |
| 503         | 01S03      | 01S03      | No rows updated/deleted                                           |
| 504         | 01S04      | 01S04      | More than one row updated/deleted                                 |
| 505         | 01S06      | 01S06      | Attempt to fetch before the result set returned the first row set |
| 506         | 07001      | 07002      | <code>SQLBindParameter</code> not used for all parameters         |
| 507         | 07005      | 07005      | Prepared statement not a cursor-specification                     |
| 508         | 07009      | 07009      | Invalid descriptor index                                          |
| 509         | 08002      | 08002      | Connection name in use                                            |
| 510         | 08003      | 08003      | Connection does not exist                                         |
| 511         | 24000      | 24000      | Invalid cursor state                                              |
| 512         | 25000      | 25000      | Invalid transaction state                                         |
| 513         | 25S01      | 25S01      | Transaction state unknown                                         |
| 514         | 34000      | 34000      | Invalid cursor name                                               |
| 515         | S1000      | HY000      | General driver defined error                                      |
| 516         | S1001      | HY001      | Memory allocation error                                           |
| 517         | S1002      | HY002      | Invalid column number                                             |
| 518         | S1003      | HY003      | Invalid application buffer type                                   |
| 519         | S1004      | HY004      | Invalid SQL data type                                             |
| 520         | S1009      | HY009      | Invalid use of null pointer                                       |
| 521         | S1010      | HY010      | Function sequence error                                           |
| 522         | S1011      | HY011      | Attribute can not be set now                                      |
| 523         | S1012      | HY012      | Invalid transaction operation code                                |

|     |       |       |                                         |
|-----|-------|-------|-----------------------------------------|
| 524 | S1013 | HY013 | Memory management error                 |
| 525 | S1015 | HY015 | No cursor name available                |
| 526 | S1024 | HY024 | Invalid attribute value                 |
| 527 | S1090 | HY090 | Invalid string or buffer length         |
| 528 | S1091 | HY091 | Invalid descriptor field identifier     |
| 529 | S1092 | HY092 | Invalid attribute/option identifier     |
| 530 | S1093 | HY093 | Invalid parameter number                |
| 531 | S1095 | HY095 | Function type out of range              |
| 532 | S1106 | HY106 | Fetch type out of range                 |
| 533 | S1117 | HY117 | Row value out of range                  |
| 534 | S1109 | HY109 | Invalid cursor position                 |
| 535 | S1C00 | HYC00 | Optional feature not implemented        |
| 0   | 21S01 | 21S01 | Column count does not match value count |
| 0   | 23000 | 23000 | Integrity constraint violation          |
| 0   | 42000 | 42000 | Syntax error or access violation        |
| 0   | 42S02 | 42S02 | Base table or view not found            |
| 0   | 42S12 | 42S12 | Index not found                         |
| 0   | 42S21 | 42S21 | Column already exists                   |
| 0   | 42S22 | 42S22 | Column not found                        |
| 0   | 08S01 | 08S01 | Communication link failure              |

## 29.1.7. Connector/ODBC Notes and Tips

Here are some common notes and tips for using Connector/ODBC within different environments, applications and tools. The notes provided here are based on the experiences of Connector/ODBC developers and users.

### 29.1.7.1. Connector/ODBC General Functionality

This section provides help with common queries and areas of functionality in MySQL and how to use them with Connector/ODBC.

#### 29.1.7.1.1. Obtaining Auto-Increment Values

Obtaining the value of column that uses `AUTO_INCREMENT` after an `INSERT` statement can be achieved in a number of different ways. To obtain the value immediately after an `INSERT`, use a `SELECT` query with the `LAST_INSERT_ID()` function.

For example, using Connector/ODBC you would execute two separate statements, the `INSERT` statement and the `SELECT` query to obtain the auto-increment value.

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
SELECT LAST_INSERT_ID();
```

If you do not require the value within your application, but do require the value as part of another `INSERT`, the entire process can be handled by executing the following statements:

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
INSERT INTO tbl2 (id,text) VALUES(LAST_INSERT_ID(),'text');
```

Certain ODBC applications (including Delphi and Access) may have trouble obtaining the auto-increment value using the previous examples. In this case, try the following statement as an alternative:

```
SELECT * FROM tbl WHERE auto IS NULL;
```

See [Section 28.2.14.3, “How to Get the Unique ID for the Last Inserted Row”](#).

#### 29.1.7.1.2. Dynamic Cursor Support

Support for the `dynamic cursor` is provided in Connector/ODBC 3.51, but dynamic cursors are not enabled by default. You can enable this function within Windows by selecting the `Enable Dynamic Cursor` checkbox within the ODBC Data Source Administrator.

On other platforms, you can enable the dynamic cursor by adding 32 to the `OPTION` value when creating the DSN.

### 29.1.7.1.3. Connector/ODBC Performance

The Connector/ODBC driver has been optimized to provide very fast performance. If you experience problems with the performance of Connector/ODBC, or notice a large amount of disk activity for simple queries, there are a number of aspects you should check:

- Ensure that `ODBC Tracing` is not enabled. With tracing enabled, a lot of information is recorded in the tracing file by the ODBC Manager. You can check, and disable, tracing within Windows using the TRACING panel of the ODBC Data Source Administrator. Within Mac OS X, check the TRACING panel of ODBC Administrator. See [Section 29.1.4.8, “Getting an ODBC Trace File”](#).
- Make sure you are using the standard version of the driver, and not the debug version. The debug version includes additional checks and reporting measures.
- Disable the Connector/ODBC driver trace and query logs. These options are enabled for each DSN, so make sure to examine only the DSN that you are using in your application. Within Windows, you can disable the Connector/ODBC and query logs by modifying the DSN configuration. Within Mac OS X and Unix, ensure that the driver trace (option value 4) and query logging (option value 524288) are not enabled.

### 29.1.7.1.4. Setting ODBC Query Timeout in Windows

For more information on how to set the query timeout on Microsoft Windows when executing queries through an ODBC connection, read the Microsoft knowledgebase document at <http://support.microsoft.com/default.aspx?scid=kb%3Ben-us%3B153756>.

### 29.1.7.2. Connector/ODBC Application Specific Tips

Most programs should work with Connector/ODBC, but for each of those listed here, there are specific notes and tips to improve or enhance the way you work with Connector/ODBC and these applications.

With all applications you should ensure that you are using the latest Connector/ODBC drivers, ODBC Manager and any supporting libraries and interfaces used by your application. For example, on Windows, using the latest version of Microsoft Data Access Components (MDAC) will improve the compatibility with ODBC in general, and with the Connector/ODBC driver.

#### 29.1.7.2.1. Using Connector/ODBC with Microsoft Applications

The majority of Microsoft applications have been tested with Connector/ODBC, including Microsoft Office, Microsoft Access and the various programming languages supported within ASP and Microsoft Visual Studio.

##### 29.1.7.2.1.1. Microsoft Access

To improve the integration between Microsoft Access and MySQL through Connector/ODBC:

- For all versions of Access, you should enable the Connector/ODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a `TIMESTAMP` column in all tables that you want to be able to update. For maximum portability, don't use a length specification in the column declaration (which is unsupported within MySQL in versions earlier than 4.1).
- You should have a primary key in each MySQL table you want to use with Access. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you can't find or update rows.
- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED#`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

Old records may still display as `#DELETED#`, but newly added/updated records are displayed properly.

- If you still get the error [Another user has changed your data](#) after adding a `TIMESTAMP` column, the following trick may help you:  
  
Don't use a `table` data sheet view. Instead, create a form with the fields you want, and use that `form` data sheet view. You should set the `DefaultValue` property for the `TIMESTAMP` column to `NOW()`. It may be a good idea to hide the `TIMESTAMP` column from view so your users are not confused.
- In some cases, Access may generate SQL statements that MySQL can't understand. You can fix this by selecting "`Query|SQLSpecific|Pass-Through`" from the Access menu.
- On Windows NT, Access reports `BLOB` columns as `OLE OBJECTS`. If you want to have `MEMO` columns instead, you should change `BLOB` columns to `TEXT` with `ALTER TABLE`.
- Access can't always handle the MySQL `DATE` column properly. If you have a problem with these, change the columns to `DATETIME`.
- If you have in Access a column defined as `BYTE`, Access tries to export this as `TINYINT` instead of `TINYINT UNSIGNED`. This gives you problems if you have values larger than 127 in the column.
- If you have very large (long) tables in Access, it might take a very long time to open them. Or you might run low on virtual memory and eventually get an `ODBC Query Failed` error and the table cannot open. To deal with this, select the following options:
  - Return Matching Rows (2)
  - Allow BIG Results (8).
 These add up to a value of 10 (`OPTION=10`).

Some external articles and tips that may be useful when using Access, ODBC and Connector/ODBC:

- Read [How to Trap ODBC Login Error Messages in Access](#)
- [Optimizing Access ODBC Applications](#)
  - [Optimizing for Client/Server Performance](#)
  - [Tips for Converting Applications to Using ODBCdirect](#)
  - [Tips for Optimizing Queries on Attached SQL Tables](#)
- For a list of tools that can be used with Access and ODBC data sources, refer to [converters](#) section for list of available tools.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about using ODBC with Access in Knowledge Base articles such as [Use MySQL-Specific Syntax with Microsoft Access](#). To subscribe to MySQL Enterprise see <http://www.mysql.com/products/enterprise/advisors.html>.

### 29.1.7.2.1.2. Microsoft Excel and Column Types

If you have problems importing data into Microsoft Excel, particularly numerical, date, and time values, this is probably because of a bug in Excel, where the column type of the source data is used to determine the data type when that data is inserted into a cell within the worksheet. The result is that Excel incorrectly identifies the content and this affects both the display format and the data when it is used within calculations.

To address this issue, use the `CONCAT()` function in your queries. The use of `CONCAT()` forces Excel to treat the value as a string, which Excel will then parse and usually correctly identify the embedded information.

However, even with this option, some data may be incorrectly formatted, even though the source data remains unchanged. Use the [Format Cells](#) option within Excel to change the format of the displayed information.

### 29.1.7.2.1.3. Microsoft Visual Basic

To be able to update a table, you must define a primary key for the table.

Visual Basic with ADO can't handle big integers. This means that some queries like `SHOW PROCESSLIST` do not work properly. The fix is to use `OPTION=16384` in the ODBC connect string or to select the [Change BIGINT columns to INT](#) option in the Connector/ODBC connect screen. You may also want to select the [Return matching rows](#) option.

**MySQL Enterprise**

MySQL Enterprise subscribers can find a discussion about using VBA in the Knowledge Base article, [MySQL-Specific Syntax with VBA](http://www.mysql.com/products/enterprise/advisors.html). To subscribe to MySQL Enterprise see <http://www.mysql.com/products/enterprise/advisors.html>.

**29.1.7.2.1.4. Microsoft Visual InterDev**

If you have a `BIGINT` in your result, you may get the error `[Microsoft][ODBC Driver Manager] Driver does not support this parameter`. Try selecting the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen.

**29.1.7.2.1.5. Visual Objects**

You should select the `Don't optimize column widths` option.

**29.1.7.2.1.6. Microsoft ADO**

When you are coding with the ADO API and Connector/ODBC, you need to pay attention to some default properties that aren't supported by the MySQL server. For example, using the `CursorLocation Property` as `adUseServer` returns a result of `-1` for the `RecordCount Property`. To have the right value, you need to set this property to `adUseClient`, as shown in the VB code here:

```
Dim myconn As New ADOConnection
Dim myrs As New Recordset
Dim mySQL As String
Dim myrows As Long

myconn.Open "DSN=MyODBCsample"
mySQL = "SELECT * from user"
myrs.Source = mySQL
Set myrs.ActiveConnection = myconn
myrs.CursorLocation = adUseClient
myrs.Open
myrows = myrs.RecordCount

myrs.Close
myconn.Close
```

Another workaround is to use a `SELECT COUNT( *)` statement for a similar query to get the correct row count.

To find the number of rows affected by a specific SQL statement in ADO, use the `RecordsAffected` property in the ADO `execute` method. For more information on the usage of `execute` method, refer to <http://msdn.microsoft.com/library/default.asp?url=/library/en-us/ado270/htm/mdmthcnnextexecute.asp>.

For information, see [ActiveX Data Objects\(ADO\) Frequently Asked Questions](#).

**29.1.7.2.1.7. Using Connector/ODBC with Active Server Pages (ASP)**

You should select the `Return matching rows` option in the DSN.

For more information about how to access MySQL via ASP using Connector/ODBC, refer to the following articles:

- [Using MyODBC To Access Your MySQL Database Via ASP](#)
- [ASP and MySQL at DWAM.NT](#)

A Frequently Asked Questions list for ASP can be found at <http://support.microsoft.com/default.aspx?scid=/Support/ActiveServer/faq/data/adofaq.asp>.

**29.1.7.2.1.8. Using Connector/ODBC with Visual Basic (ADO, DAO and RDO) and ASP**

Some articles that may help with Visual Basic and ASP:

- [MySQL BLOB columns and Visual Basic 6](#) by Mike Hillyer (<mike@openwin.org>).
- [How to map Visual basic data type to MySQL types](#) by Mike Hillyer (<mike@openwin.org>).

**29.1.7.2.2. Using Connector/ODBC with Borland Applications**

With all Borland applications where the Borland Database Engine (BDE) is used, follow these steps to improve compatibility:

- Update to BDE 3.2 or newer.
- Enable the `Don't optimize column widths` option in the DSN.
- Enabled the `Return matching rows` option in the DSN.

#### 29.1.7.2.2.1. Using Connector/ODBC with Borland Builder 4

When you start a query, you can use the `Active` property or the `Open` method. Note that `Active` starts by automatically issuing a `SELECT * FROM ...` query. That may not be a good thing if your tables are large.

#### 29.1.7.2.2.2. Using Connector/ODBC with Delphi

Also, here is some potentially useful Delphi code that sets up both an ODBC entry and a BDE entry for Connector/ODBC. The BDE entry requires a BDE Alias Editor that is free at a Delphi Super Page near you. (Thanks to Bryan Brunton <bryan@flesherfab.com> for this):

```
fReg:= TRegistry.Create;
fReg.OpenKey('\Software\ODBC\ODBC.INI\DocumentsFab', True);
fReg.WriteString('Database', 'Documents');
fReg.WriteString('Description', '');
fReg.WriteString('Driver', 'C:\WINNT\System32\myodbc.dll');
fReg.WriteString('Flag', '1');
fReg.WriteString('Password', '');
fReg.WriteString('Port', '');
fReg.WriteString('Server', 'xmark');
fReg.WriteString('User', 'winuser');
fReg.OpenKey('\Software\ODBC\ODBC.INI\ODBC Data Sources', True);
fReg.WriteString('DocumentsFab', 'MySQL');
fReg.CloseKey;

```

#### 29.1.7.2.2.3. Using Connector/ODBC with C++ Builder

Tested with BDE 3.0. The only known problem is that when the table schema changes, query fields are not updated. BDE, however, does not seem to recognize primary keys, only the index named `PRIMARY`, although this has not been a problem.

#### 29.1.7.2.3. Using Connector/ODBC with ColdFusion

The following information is taken from the ColdFusion documentation:

Use the following information to configure ColdFusion Server for Linux to use the `unixODBC` driver with Connector/ODBC for MySQL data sources. You can download Connector/ODBC at <http://dev.mysql.com/downloads/connector/odbc/>.

ColdFusion version 4.5.1 allows you to use the ColdFusion Administrator to add the MySQL data source. However, the driver is not included with ColdFusion version 4.5.1. Before the MySQL driver appears in the ODBC data sources drop-down list, you must build and copy the Connector/ODBC driver to `/opt/coldfusion/lib/libmyodbc.so`.

The Contrib directory contains the program `mysdn-xxx.zip` which allows you to build and remove the DSN registry file for the Connector/ODBC driver on ColdFusion applications.

For more information and guides on using ColdFusion and Connector/ODBC, see the following external sites:

- [Troubleshooting Data Sources and Database Connectivity for Unix Platforms](#).

#### 29.1.7.2.4. Using Connector/ODBC with OpenOffice.org

Open Office (<http://www.openoffice.org>) [How-to: MySQL + OpenOffice](#). [How-to: OpenOffice + MyODBC + unixODBC](#).

### 29.1.7.2.5. Using Connector/ODBC with Sambar Server

Sambar Server (<http://www.sambarserver.info>) [How-to: MyODBC + SambarServer + MySQL](#).

### 29.1.7.2.6. Using Connector/ODBC with Pervasive Software DataJunction

You have to change it to output `VARCHAR` rather than `ENUM`, as it exports the latter in a manner that causes MySQL problems.

### 29.1.7.2.7. Using Connector/ODBC with SunSystems Vision

You should select the `Return matching rows` option.

## 29.1.7.3. Connector/ODBC Errors and Resolutions (FAQ)

The following section details some common errors and their suggested fix or alternative solution. If you are still experiencing problems, use the Connector/ODBC mailing list; see [Section 29.1.8.1, "Connector/ODBC Community Support"](#).

Many problems can be resolved by upgrading your Connector/ODBC drivers to the latest available release. On Windows, you should also make sure that you have the latest versions of the Microsoft Data Access Components (MDAC) installed.

### Questions

- [30.1.7.3.1](#): I have installed Connector/ODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the Connector/ODBC driver does not appear in `ODBC Data Source Administrator`.
- [30.1.7.3.2](#): When connecting or using the TEST button in `ODBC Data Source Administrator` I get error 10061 (Cannot connect to server)
- [30.1.7.3.3](#): The following error is reported when using transactions: `Transactions are not enabled`
- [30.1.7.3.4](#): Access reports records as `#DELETED#` when inserting or updating records in linked tables.
- [30.1.7.3.5](#): How do I handle Write Conflicts or Row Location errors?
- [30.1.7.3.6](#): Exporting data from Access 97 to MySQL reports a `Syntax Error`.
- [30.1.7.3.7](#): Exporting data from Microsoft DTS to MySQL reports a `Syntax Error`.
- [30.1.7.3.8](#): Using ODBC.NET with Connector/ODBC, while fetching empty string (0 length), it starts giving the `SQL_NO_DATA` exception.
- [30.1.7.3.9](#): Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.
- [30.1.7.3.10](#): Using the `AppendChunk()` or `GetChunk()` ADO methods, the `Multiple-step operation generated errors. Check each status value` error is returned.
- [30.1.7.3.11](#): Access Returns `Another user had modified the record that you have modified while editing records on a Linked Table`.
- [30.1.7.3.12](#): When linking an application directly to the Connector/ODBC library under Unix/Linux, the application crashes.
- [30.1.7.3.13](#): Applications in the Microsoft Office suite are unable to update tables that have `DATE` or `TIMESTAMP` columns.
- [30.1.7.3.14](#): When connecting Connector/ODBC 5.x (Beta) to a MySQL 4.x server, the error `1044 Access denied for user 'xxx'@'%' to database 'information_schema'` is returned.
- [30.1.7.3.15](#): When calling `SQLTables`, the error `S1T00` is returned, but I cannot find this in the list of error numbers for Connector/ODBC.
- [30.1.7.3.16](#): When linking to tables in Access 2000 and generating links to tables programmatically, rather than through the table designer interface, you may get errors about tables not existing.
- [30.1.7.3.17](#): When I try to use batched statements, the execution of the batched statements fails.
- [30.1.7.3.18](#): When connecting to a MySQL server using ADODB and Excel, occasionally the application fails to communicate with the server and the error `Got an error reading communication packets` appears in the error log.
- [30.1.7.3.19](#): When using some applications to access a MySQL server using C/ODBC and outer joins, an error is reported re-

garding the Outer Join Escape Sequence.

- **30.1.7.3.20:** I can correctly store extended characters in the database (Hebrew/CJK) using C/ODBC 5.1, but when I retrieve the data, the text is not formatted correctly and I get garbled characters.
- **30.1.7.3.21:** I have a duplicate MySQL Connector/ODBC entry within my **INSTALLED PROGRAMS** list, but I cannot delete one of them.
- **30.1.7.3.22:** When submitting queries with parameter binding using **UPDATE**, my field values are being truncated to 255 characters.

## Questions and Answers

### **30.1.7.3.1: I have installed Connector/ODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the Connector/ODBC driver does not appear in ODBC Data Source Administrator.**

This is not a bug, but is related to the way Windows x64 editions operate with the ODBC driver. On Windows x64 editions, the Connector/ODBC driver is installed in the `%SystemRoot%\SysWOW64` folder. However, the default **ODBC Data Source Administrator** that is available through the **Administrative Tools** or **Control Panel** in Windows x64 Editions is located in the `%SystemRoot%\system32` folder, and only searches this folder for ODBC drivers.

On Windows x64 editions, you should use the ODBC administration tool located at `%SystemRoot%\SysWOW64\odbcad32.exe`, this will correctly locate the installed Connector/ODBC drivers and enable you to create a Connector/ODBC DSN.

This issue was originally reported as [Bug#20301](#).

### **30.1.7.3.2: When connecting or using the TEST button in ODBC Data Source Administrator I get error 10061 (Cannot connect to server)**

This error can be raised by a number of different issues, including server problems, network problems, and firewall and port blocking problems. For more information, see [Section B.1.2.2, "Can't connect to \[local\] MySQL server"](#).

### **30.1.7.3.3: The following error is reported when using transactions: Transactions are not enabled**

This error indicates that you are trying to use transactions with a MySQL table that does not support transactions. Transactions are supported within MySQL when using the **InnoDB** database engine. In versions of MySQL before Mysql 5.1 you may also use the **BDB** engine.

You should check the following before continuing:

- Verify that your MySQL server supports a transactional database engine. Use **SHOW ENGINES** to obtain a list of the available engine types.
- Verify that the tables you are updating use a transaction database engine.
- Ensure that you have not enabled the **disable transactions** option in your DSN.

### **30.1.7.3.4: Access reports records as #DELETED# when inserting or updating records in linked tables.**

If the inserted or updated records are shown as **#DELETED#** in the access, then:

- If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC (**Microsoft Data Access Components**) from <http://support.microsoft.com/kb/110093>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified.

You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be found at <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114>. This fixes some cases where columns are marked as **#DELETED#** in Access.

- For all versions of Access, you should enable the Connector/ODBC **Return matching rows** option. For Access 2.0, you should additionally enable the **Simulate ODBC 1.0** option.
- You should have a timestamp in all tables that you want to be able to update.
- You should have a primary key in the table. If not, new or updated rows may show up as **#DELETED#**.
- Use only **DOUBLE** float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or

updated rows may show up as #DELETED# or that you can't find or update rows.

- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as #DELETED#. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

Old records still display as #DELETED#, but newly added/updated records are displayed properly.

#### 30.1.7.3.5: How do I handle Write Conflicts or Row Location errors?

If you see the following errors, select the `Return Matching Rows` option in the DSN configuration dialog, or specify `OPTION=2`, as the connection parameter:

```
Write Conflict. Another user has changed your data.
Row cannot be located for updating. Some values may have been changed
since it was last read.
```

#### 30.1.7.3.6: Exporting data from Access 97 to MySQL reports a Syntax Error.

This error is specific to Access 97 and versions of Connector/ODBC earlier than 3.51.02. Update to the latest version of the Connector/ODBC driver to resolve this problem.

#### 30.1.7.3.7: Exporting data from Microsoft DTS to MySQL reports a Syntax Error.

This error occurs only with MySQL tables using the `TEXT` or `VARCHAR` data types. You can fix this error by upgrading your Connector/ODBC driver to version 3.51.02 or higher.

#### 30.1.7.3.8: Using ODBC.NET with Connector/ODBC, while fetching empty string (0 length), it starts giving the SQL\_NO\_DATA exception.

You can get the patch that addresses this problem from <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q319243>.

#### 30.1.7.3.9: Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.

This error occurs because the `COUNT(*)` expression is returning a `BIGINT`, and ADO can't make sense of a number this big. Select the `Change BIGINT columns to INT` option (option value 16384).

#### 30.1.7.3.10: Using the `AppendChunk()` or `GetChunk()` ADO methods, the Multiple-step operation generated errors. Check each status value error is returned.

The `GetChunk()` and `AppendChunk()` methods from ADO doesn't work as expected when the cursor location is specified as `adUseServer`. On the other hand, you can overcome this error by using `adUseClient`.

A simple example can be found from [http://www.dwam.net/iishelp/ado/docs/adomth02\\_4.htm](http://www.dwam.net/iishelp/ado/docs/adomth02_4.htm)

#### 30.1.7.3.11: Access Returns Another user had modified the record that you have modified while editing records on a Linked Table.

In most cases, this can be solved by doing one of the following things:

- Add a primary key for the table if one doesn't exist.
- Add a timestamp column if one doesn't exist.
- Only use double-precision float fields. Some programs may fail when they compare single-precision floats.

If these strategies don't help, you should start by making a log file from the ODBC manager (the log you get when requesting logs from ODBCADMIN) and a Connector/ODBC log to help you figure out why things go wrong. For instructions, see [Section 29.1.4.8, "Getting an ODBC Trace File"](#).

#### 30.1.7.3.12: When linking an application directly to the Connector/ODBC library under Unix/Linux, the application crashes.

Connector/ODBC 3.51 under Unix/Linux is not compatible with direct application linking. You must use a driver manager, such as iODBC or unixODBC to connect to an ODBC source.

**30.1.7.3.13: Applications in the Microsoft Office suite are unable to update tables that have `DATE` or `TIMESTAMP` columns.**

This is a known issue with Connector/ODBC. You must ensure that the field has a default value (rather than `NULL` and that the default value is non-zero (i.e. the default value is not `0000-00-00 00:00:00`).

**30.1.7.3.14: When connecting Connector/ODBC 5.x (Beta) to a MySQL 4.x server, the error `1044 Access denied for user 'xxx'@'%' to database 'information_schema'` is returned.**

Connector/ODBC 5.x is designed to work with MySQL 5.0 or later, taking advantage of the `INFORMATION_SCHEMA` database to determine data definition information. Support for MySQL 4.1 is planned for the final release.

**30.1.7.3.15: When calling `SQLTables`, the error `S1T00` is returned, but I cannot find this in the list of error numbers for Connector/ODBC.**

The `S1T00` error indicates that a general timeout has occurred within the ODBC system and is not a MySQL error. Typically it indicates that the connection you are using is stale, the server is too busy to accept your request or that the server has gone away.

**30.1.7.3.16: When linking to tables in Access 2000 and generating links to tables programmatically, rather than through the table designer interface, you may get errors about tables not existing.**

There is a known issue with a specific version of the `msjet40.dll` that exhibits this issue. The version affected is 4.0.9025.0. Reverting to an older version will enable you to create the links. If you have recently updated your version, check your `WINDOWS` directory for the older version of the file and copy it to the drivers directory.

**30.1.7.3.17: When I try to use batched statements, the execution of the batched statements fails.**

Batched statement support was added in 3.51.18. Support for batched statements is not enabled by default. You must enable option `FLAG_MULTI_STATEMENTS`, value 67108864, or select the `ALLOW MULTIPLE STATEMENTS` flag within a GUI configuration.

**30.1.7.3.18: When connecting to a MySQL server using ADODB and Excel, occasionally the application fails to communicate with the server and the error `Got an error reading communication packets` appears in the error log.**

This error may be related to Keyboard Logger 1.1 from PanteraSoft.com, which is known to interfere with the network communication between MySQL Connector/ODBC and MySQL.

**30.1.7.3.19: When using some applications to access a MySQL server using C/ODBC and outer joins, an error is reported regarding the Outer Join Escape Sequence.**

This is a known issue with MySQL Connector/ODBC which is not correctly parsing the "Outer Join Escape Sequence", as per the specs at [Microsoft ODBC Specs](#). Currently, Connector/ODBC will return value `> 0` when asked for `SQL_OJ_CAPABILITIES` even though no parsing takes place in the driver to handle the outer join escape sequence.

**30.1.7.3.20: I can correctly store extended characters in the database (Hebrew/CJK) using C/ODBC 5.1, but when I retrieve the data, the text is not formatted correctly and I get garbled characters.**

When using ASP and UTF8 characters you should add the following to your ASP files to ensure that the data returned is correctly encoded:

```
Response.CodePage = 65001
Response.CharSet = "utf-8"
```

**30.1.7.3.21: I have a duplicate MySQL Connector/ODBC entry within my INSTALLED PROGRAMS list, but I cannot delete one of them.**

This problem can occur when you upgrade an existing Connector/ODBC installation, rather than removing and then installing the updated version.

### Warning

To fix the problem you should use any working uninstallers to remove existing installations and then may have to edit the contents of the registry. Make sure you have a backup of your registry information before attempting any editing of the registry contents.

**30.1.7.3.22: When submitting queries with parameter binding using `UPDATE`, my field values are being truncated to 255 characters.**

You should ensure that the `FLAG_BIG_PACKETS` option is set for your connection. This removes the 255 character limitation on bound parameters.

## 29.1.8. Connector/ODBC Support

There are many different places where you can get support for using Connector/ODBC. You should always try the Connector/ODBC Mailing List or Connector/ODBC Forum. See [Section 29.1.8.1, “Connector/ODBC Community Support”](#), for help before reporting a specific bug or issue to MySQL.

### 29.1.8.1. Connector/ODBC Community Support

MySQL AB provides assistance to the user community by means of its mailing lists. For Connector/ODBC-related issues, you can get help from experienced users by using the `<myodbc@lists.mysql.com>` mailing list. Archives are available online at <http://lists.mysql.com/myodbc>.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.6.1, “MySQL Mailing Lists”](#).

Community support from experienced users is also available through the [ODBC Forum](#). You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.6.2, “MySQL Community Support at the MySQL Forums”](#).

### 29.1.8.2. How to Report Connector/ODBC Problems or Bugs

If you encounter difficulties or problems with Connector/ODBC, you should start by making a log file from the [ODBC Manager](#) (the log you get when requesting logs from [ODBC ADMIN](#)) and Connector/ODBC. The procedure for doing this is described in [Section 29.1.4.8, “Getting an ODBC Trace File”](#).

Check the Connector/ODBC trace file to find out what could be wrong. You should be able to determine what statements were issued by searching for the string `>mysql_real_query` in the `myodbc.log` file.

You should also try issuing the statements from the `mysql` client program or from `admindemo`. This helps you determine whether the error is in Connector/ODBC or MySQL.

If you find out something is wrong, please only send the relevant rows (maximum 40 rows) to the `myodbc` mailing list. See [Section 1.6.1, “MySQL Mailing Lists”](#). Please never send the whole Connector/ODBC or ODBC log file!

You should ideally include the following information with the email:

- Operating system and version
- Connector/ODBC version
- ODBC Driver Manager type and version
- MySQL server version
- ODBC trace from Driver Manager
- Connector/ODBC log file from Connector/ODBC driver
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem!

Also, before posting the bug, check the MyODBC mailing list archive at <http://lists.mysql.com/myodbc>.

If you are unable to find out what's wrong, the last option is to create an archive in `tar` or Zip format that contains a Connector/ODBC trace file, the ODBC log file, and a `README` file that explains the problem. You can send this to <ftp://ftp.mysql.com/pub/mysql/upload/>. Only MySQL engineers have access to the files you upload, and we are very discreet with the data.

If you can create a program that also demonstrates the problem, please include it in the archive as well.

If the program works with another SQL server, you should include an ODBC log file where you perform exactly the same SQL statements so that we can compare the results between the two systems.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

### 29.1.8.3. How to Submit a Connector/ODBC Patch

You can send a patch or suggest a better solution for any existing code or problems by sending a mail message to

[<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com).

#### 29.1.8.4. Connector/ODBC Change History

The Connector/ODBC Change History (Changelog) is located with the main Changelog for MySQL. See [Section C.2, “MySQL Connector/ODBC \(MyODBC\) Change History”](#).

#### 29.1.8.5. Credits

These are the developers that have worked on the Connector/ODBC and Connector/ODBC 3.51 Drivers from MySQL AB.

- Michael (Monty) Widenius
- Venu Anuganti
- Peter Harvey

## 29.2. MySQL Connector/NET

Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. Connector/NET is a fully managed ADO.NET driver written in 100% pure C#.

Connector/NET includes full support for:

- MySQL 5.0 features (such as stored procedures)
- MySQL 4.1 features (server-side prepared statements, Unicode, and shared memory access, and so forth)
- Large-packet support for sending and receiving rows and BLOBs up to 2 gigabytes in size.
- Protocol compression which allows for compressing the data stream between the client and server.
- Support for connecting using TCP/IP sockets, named pipes, or shared memory on Windows.
- Support for connecting using TCP/IP sockets or Unix sockets on Unix.
- Support for the Open Source Mono framework developed by Novell.
- Fully managed, does not utilize the MySQL client library.

This document is intended as a user's guide to Connector/NET and includes a full syntax reference. Syntax information is also included within the [Documentation.chm](#) file included with the Connector/NET distribution.

If you are using MySQL 5.0 or later, and Visual Studio as your development environment, you may want also want to use the MySQL Visual Studio Plugin. The plugin acts as a DDEX (Data Designer Extensibility) provider, enabling you to use the data design tools within Visual Studio to manipulate the schema and objects within a MySQL database. For more information, see [Section 29.3, “MySQL Visual Studio Plugin”](#).

### Note

Connector/NET 5.1.2 and later include the Visual Studio Plugin by default.

#### Key topics:

- For connection string properties when using the `MySqlConnection` class, see [Section 29.2.3.3.3, “ConnectionString”](#).

### 29.2.1. Connector/NET Versions

There are currently three versions of Connector/NET available:

- Connector/NET 1.0 includes support for MySQL 4.0, and MySQL 5.0 features, and full compatibility with the ADO.NET driver interface.

Connector/NET 5.0 includes support for MySQL 4.0, MySQL 4.1, MySQL 5.0 and MySQL 5.1 features. Connector/NET 5.0 also includes full support for the ADO.Net 2.0 interfaces and subclasses, includes support for the usage advisor and performance monitor (PerfMon) hooks.

Connector/NET 5.1 includes support for MySQL 4.0, MySQL 5.0, MySQL 5.1 and MySQL 6.0 (Falcon Preview) features. Connector/NET 5.1 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to `GetSchema`. Connector/NET 5.1 also includes the Visual Studio Plugin as a standard installable component.

**Note**

Version numbers for MySQL products are formatted as X.X.X. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.XX.XX. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

## 29.2.2. Connector/NET Installation

Connector/NET runs on any platform that supports the .NET framework. The .NET framework is primarily supported on recent versions of Microsoft Windows, and is supported on Linux through the Open Source Mono framework (see <http://www.mono-project.com>).

Connector/NET is available for download from <http://dev.mysql.com/downloads/connector/net/1.0.html>.

### 29.2.2.1. Installing Connector/NET on Windows

On Windows, installation is supported either through a binary installation process or by downloading a Zip file with the Connector/NET components.

Before installing, you should ensure that your system is up to date, including installing the latest version of the .NET Framework.

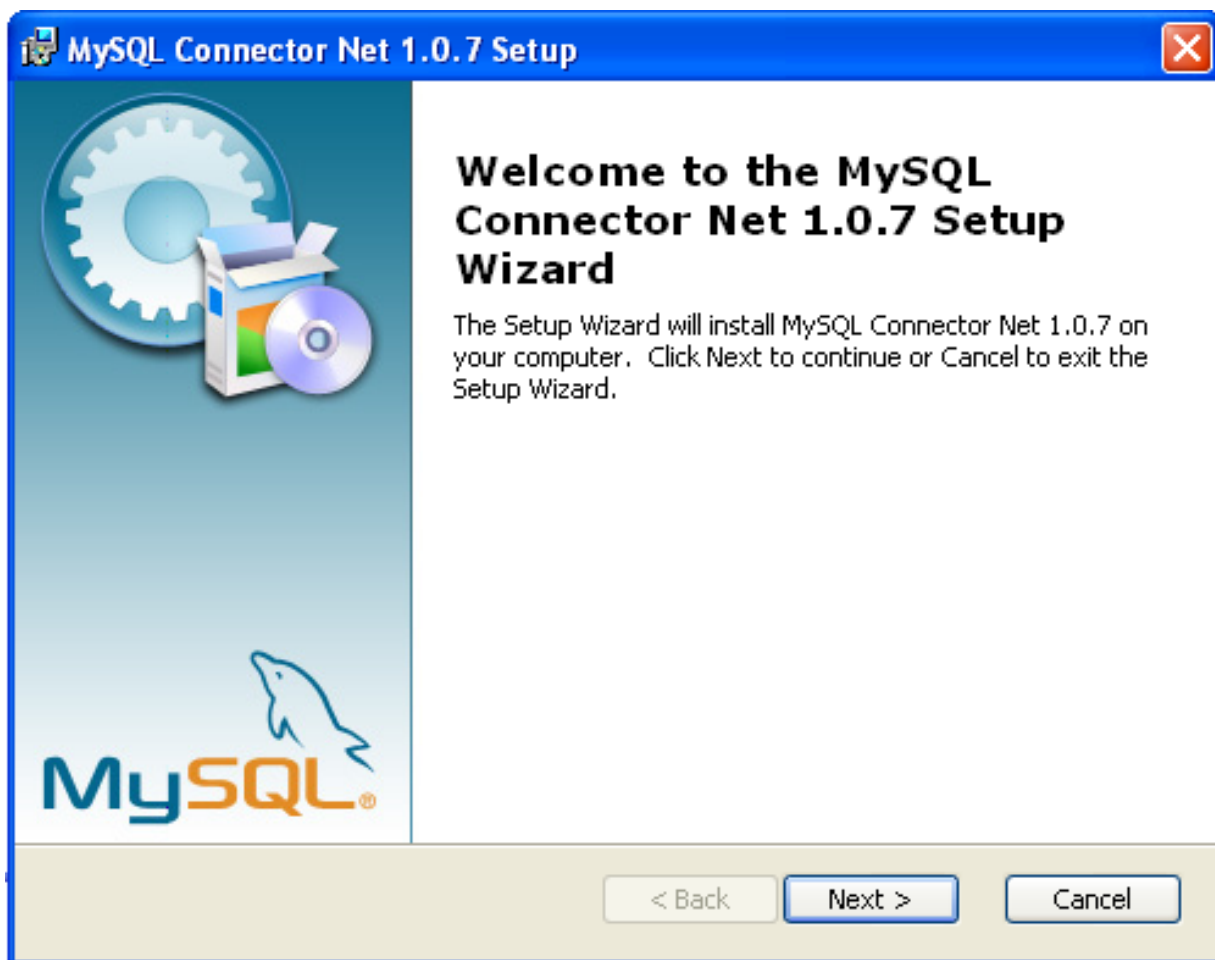

#### 29.2.2.1.1. Installing Connector/NET using the Installer

Using the installer is the most straightforward method of installing Connector/NET on Windows and the installed components include the source code, test code and full reference documentation.

Connector/NET is installed through the use of a Windows Installer (`.msi`) installation package, which can be used to install Connector/NET on all Windows operating systems. The MSI package is contained within a ZIP archive named `mysql-connector-net-version.zip`, where `version` indicates the Connector/NET version.

To install Connector/NET:

1. Double click on the MSI installer file extracted from the Zip you downloaded. Click NEXT to start the installation.

2. You must choose the type of installation that you want to perform.

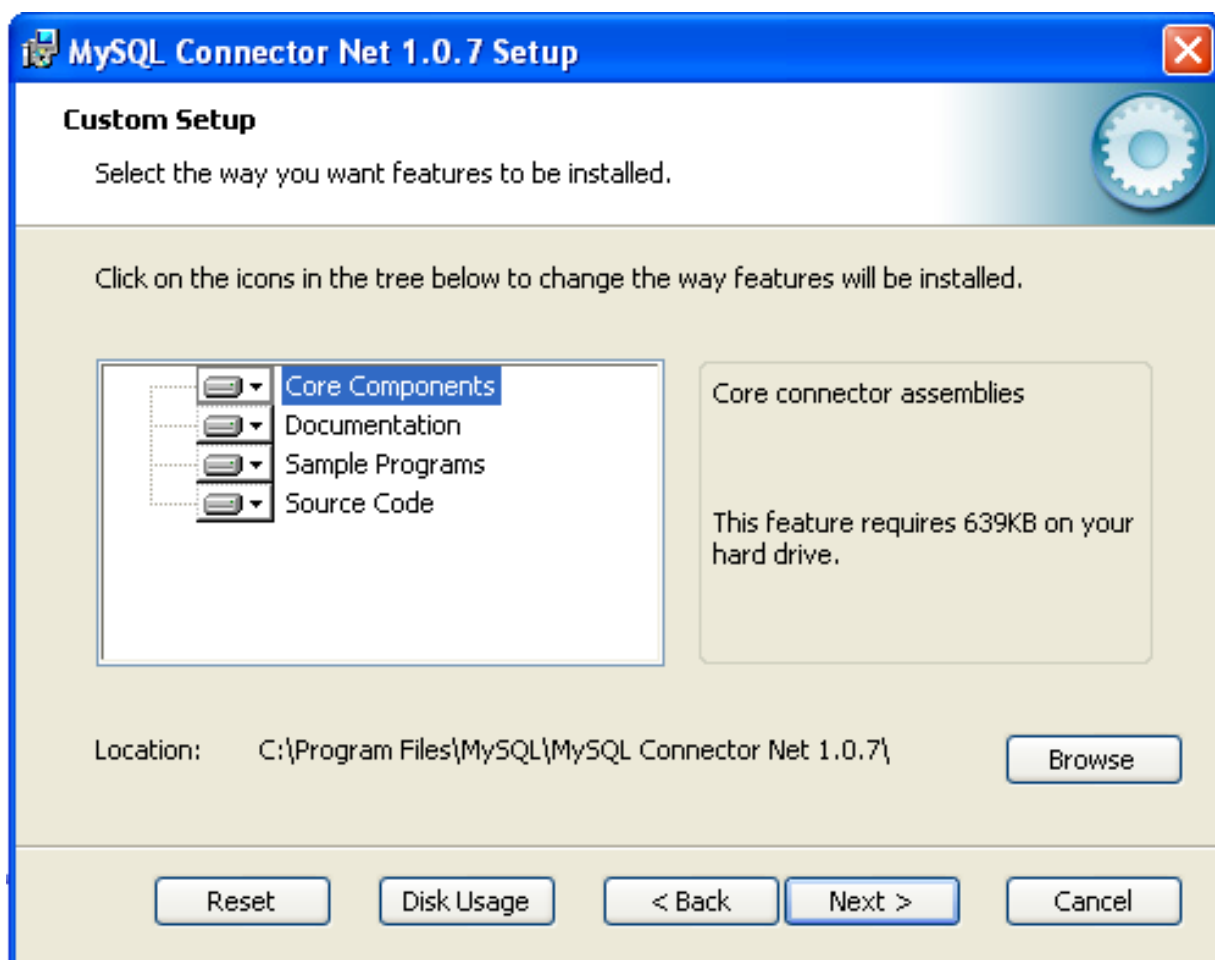

For most situations, the Typical installation will be suitable. Click the TYPICAL button and proceed to Step 5. A Complete installation installs all the available files. To conduct a Complete installation, click the COMPLETE button and proceed to step 5. If you want to customize your installation, including choosing the components to install and some installation options, click the CUSTOM button and proceed to Step 3.

The Connector/NET installer will register the connector within the Global Assembly Cache (GAC) - this will make the Connector/NET component available to all applications, not just those where you explicitly reference the Connector/NET component. The installer will also create the necessary links in the Start menu to the documentation and release notes.

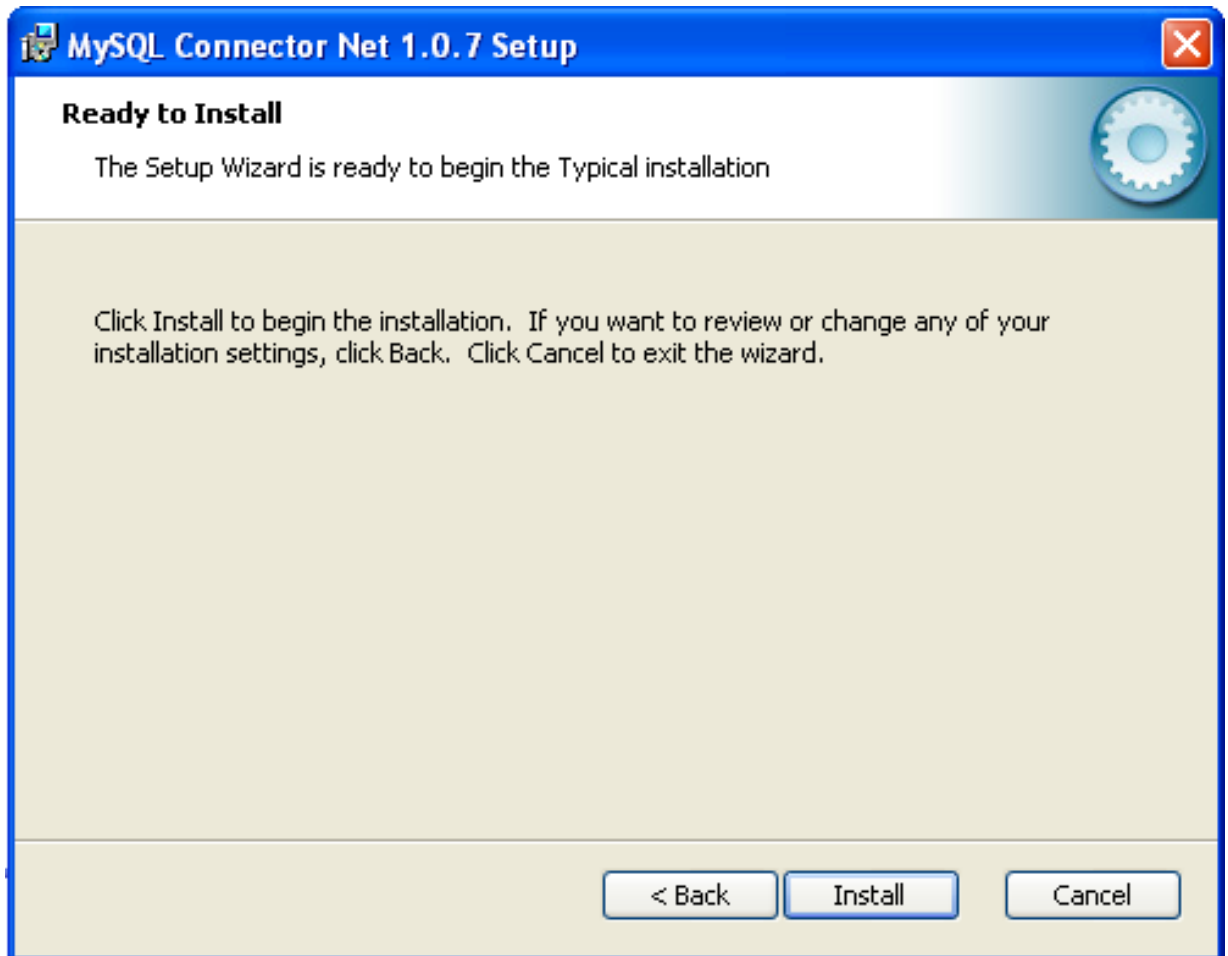

3. If you have chosen a custom installation, you can select the individual components that you want to install, including the core interface component, supporting documentation (a CHM file) samples and examples and the source code. Select the items, and their installation level, and then click NEXT to continue the installation.

#### Note

For Connector/NET 1.0.8 or lower and Connector 5.0.4 and lower the installer will attempt to install binaries for both 1.x and 2.x of the .NET Framework. If you only have one version of the framework installed, the connector installation may fail. If this happens, you can choose the framework version to be installed through the custom installation step.

4. You will be given a final opportunity to confirm the installation. Click **INSTALL** to copy and install the files onto your machine.

5. Once the installation has been completed, click FINISH to exit the installer.

Unless you choose otherwise, Connector/NET is installed in `C:\Program Files\MySQL\MySQL Connector Net X.X.X`, where `X.X.X` is replaced with the version of Connector/NET you are installing. New installations do not overwrite existing versions of Connector/NET.

Depending on your installation type, the installed components will include some or all of the following components:

- `bin` - Connector/NET MySQL libraries for different versions of the .NET environment.
- `docs` - contains a CHM of the Connector/NET documentation.
- `samples` - sample code and applications that use the Connector/NET component.
- `src` - the source code for the Connector/NET component.

You may also use the `/quiet` or `/q` command-line option with the `msiexec` tool to install the Connector/NET package automatically (using the default options) with no notification to the user. Using this option you cannot select options and no prompts, messages or dialog boxes will be displayed.

```
C:\> msiexec /package connector-net.msi /quiet
```

To provide a progress bar to the user during automatic installation, but still without presenting the user with a dialog box of the ability to select options, use the `/passive` option.

### 29.2.2.1.2. Installing Connector/NET using the Zip package

If you are having problems running the installer, you can download a .zip file without an installer as an alternative. That file is called `mysql-connector-net-version-noinstall.zip`. Once downloaded, you can extract the files to a location of

your choice.

The .zip file contains the following directories:

- `bin` - Connector/NET MySQL libraries for different versions of the .NET environment.
- `doc` - contains a CHM of the Connector/NET documentation.
- `Samples` - sample code and applications that use the Connector/NET component.
- `mysqlclient` - the source code for the Connector/NET component.
- `testsuite` - the test suite used to verify the operation of the Connector/NET component.

### 29.2.2.2. Installing Connector/NET on Unix with Mono

There is no installer available for installing the Connector/NET component on your Unix installation. However, the installation is very simple. Before installing, please ensure that you have a working Mono project installation.

Note that you should only install the Connector/NET component on Unix environments where you want to connect to a MySQL server through the Mono project. If you are deploying or developing on a different environment such as Java or Perl then you should use a more appropriate connectivity component. See [Chapter 29, Connectors](#), or [Chapter 28, APIs and Libraries](#), for more information.

To install Connector/NET on Unix/Mono:

1. Download the `mysql-connector-net-version-noinstall.zip` and extract the contents.
2. Copy the `MySql.Data.dll` file to your Mono project installation folder.
3. You must register the Connector/NET component in the Global Assembly Cache using the `gacutil` command:

```
shell> gacutil /i MySql.Data.dll
```

Once installed, applications that are compiled with the Connector/NET component need no further changes. However, you must ensure that when you compile your applications you include the Connector/NET component using the `-r:MySqlData.dll` command-line option.

### 29.2.2.3. Installing Connector/NET using the Source

#### Caution

You should read this section only if you are interested in helping us test our new code. If you just want to get Connector/NET up and running on your system, you should use a standard release distribution.

To be able to access the Connector/NET source tree, you must have Subversion installed. Subversion is freely available from <http://subversion.tigris.org/>.

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To checkout out the Connector/NET sources, change to the directory where you want the copy of the Connector/NET tree to be stored, then use the following command:

```
shell> svn co
http://svn.mysql.com/svnpublic/connector-net
```

A Visual Studio project is included in the source which you can use to build Connector/NET.

## 29.2.3. Connector/NET Examples and Usage Guide

Connector/NET comprises several classes that are used to connect to the database, execute queries and statements, and manage query results.

The following are the major classes of Connector/NET:

- [MySqlCommand](#) : Represents an SQL statement to execute against a MySQL database.
- [MySqlCommandBuilder](#) : Automatically generates single-table commands used to reconcile changes made to a DataSet with the associated MySQL database.
- [MySqlConnection](#) : Represents an open connection to a MySQL Server database.
- [MySqlDataAdapter](#) : Represents a set of data commands and a database connection that are used to fill a data set and update a MySQL database.
- [MySqlDataReader](#) : Provides a means of reading a forward-only stream of rows from a MySQL database.
- [MySqlException](#) : The exception that is thrown when MySQL returns an error.
- [MySqlHelper](#) : Helper class that makes it easier to work with the provider.
- [MySqlTransaction](#) : Represents an SQL transaction to be made in a MySQL database.

This section contains basic information and examples for each of the above classes. For a more detailed reference guide please see [Section 29.2.4, "Connector/NET Reference"](#).

### 29.2.3.1. Using MySqlCommand

Represents a SQL statement to execute against a MySQL database. This class cannot be inherited.

[MySqlCommand](#)  features the following methods for executing commands at a MySQL database:

| Item                              | Description                                                                 |
|-----------------------------------|-----------------------------------------------------------------------------|
| <a href="#"> ExecuteReader </a>   | Executes commands that return rows.                                         |
| <a href="#"> ExecuteNonQuery </a> | Executes commands such as SQL INSERT, DELETE, and UPDATE statements.        |
| <a href="#"> ExecuteScalar </a>   | Retrieves a single value (for example, an aggregate value) from a database. |

You can reset the  [CommandText](#)  property and reuse the  [MySqlCommand](#)  object. However, you must close the  [MySqlDataReader](#)  before you can execute a new or previous command.

If a  [MySqlException](#)  is generated by the method executing a  [MySqlCommand](#) , the  [MySqlConnection](#)  remains open. It is the responsibility of the programmer to close the connection.

#### Note

Prior versions of the provider used the '@' symbol to mark parameters in SQL. This is incompatible with MySQL user variables, so the provider now uses the '?' symbol to locate parameters in SQL. To support older code, you can set 'old syntax=yes' on your connection string. If you do this, please be aware that an exception will not be thrown if you fail to define a parameter that you intended to use in your SQL.

#### Examples

The following example creates a  [MySqlCommand](#)  and a  [MySqlConnection](#) . The  [MySqlConnection](#)  is opened and set as the  [Connection](#)  for the  [MySqlCommand](#) . The example then calls  [ExecuteNonQuery](#) , and closes the connection. To accomplish this, the  [ExecuteNonQuery](#)  is passed a connection string and a query string that is a SQL INSERT statement.

Visual Basic example:

```
Public Sub InsertRow(myConnectionString As String)
 " If the connection string is null, use a default.
 If myConnectionString = "" Then
 myConnectionString = "Database=Test;Data Source=localhost;User Id=username;Password=pass"
 End If
 Dim myConnection As New MySqlConnection(myConnectionString)
 Dim myInsertQuery As String = "INSERT INTO Orders (id, customerId, amount) Values(1001, 23, 30.66)"
 Dim myCommand As New MySqlCommand(myInsertQuery)
 myCommand.Connection = myConnection
 myConnection.Open()
 myCommand.ExecuteNonQuery()
 myCommand.Connection.Close()
End Sub
```

C# example:

```
public void InsertRow(string myConnectionString)
{
 // If the connection string is null, use a default.
 if(myConnectionString == "")
 {
 myConnectionString = "Database=Test;Data Source=localhost;User Id=username;Password=pass";
 }
 MySqlConnection myConnection = new MySqlConnection(myConnectionString);
 string myInsertQuery = "INSERT INTO Orders (id, customerId, amount) Values(1001, 23, 30.66)";
 MySqlCommand myCommand = new MySqlCommand(myInsertQuery);
 myCommand.Connection = myConnection;
 myConnection.Open();
 myCommand.ExecuteNonQuery();
 myCommand.Connection.Close();
}
```

### 29.2.3.1.1. Class MySqlCommand Constructor Form 1

#### Overload methods for MySqlCommand

Initializes a new instance of the MySqlCommand class.

#### Examples

The following example creates a MySqlCommand and sets some of its properties.

#### Note

This example shows how to use one of the overloaded versions of the [MySqlCommand](#) constructor. For other examples that might be available, see the individual overload topics.

Visual Basic example:

```
Public Sub CreateMySqlCommand()
 Dim myConnection As New MySqlConnection _
 ("Persist Security Info=False;database=test;server=myServer")
 myConnection.Open()
 Dim myTrans As MySqlTransaction = myConnection.BeginTransaction()
 Dim mySelectQuery As String = "SELECT * FROM MyTable"
 Dim myCommand As New MySqlCommand(mySelectQuery, myConnection, myTrans)
 myCommand.CommandTimeout = 20
End Sub
```

C# example:

```
public void CreateMySqlCommand()
{
 MySqlConnection myConnection = new MySqlConnection("Persist Security Info=False;
 database=test;server=myServer");
 myConnection.Open();
 MySqlTransaction myTrans = myConnection.BeginTransaction();
 string mySelectQuery = "SELECT * FROM myTable";
 MySqlCommand myCommand = new MySqlCommand(mySelectQuery, myConnection, myTrans);
 myCommand.CommandTimeout = 20;
}
```

C++ example:

```
public:
void CreateMySqlCommand()
{
 MySqlConnection* myConnection = new MySqlConnection(S"Persist Security Info=False;
 database=test;server=myServer");
 myConnection->Open();
 MySqlTransaction* myTrans = myConnection->BeginTransaction();
 String* mySelectQuery = S"SELECT * FROM myTable";
 MySqlCommand* myCommand = new MySqlCommand(mySelectQuery, myConnection, myTrans);
 myCommand->CommandTimeout = 20;
};
```

Initializes a new instance of the MySqlCommand class.

The base constructor initializes all fields to their default values. The following table shows initial property values for an instance of [MySqlCommand](#).

| Properties                     | Initial Value      |
|--------------------------------|--------------------|
| <a href="#">CommandText</a>    | empty string ("" ) |
| <a href="#">CommandTimeout</a> | 0                  |
| <a href="#">CommandType</a>    | CommandType.Text   |
| <a href="#">Connection</a>     | Null               |

You can change the value for any of these properties through a separate call to the property.

### Examples

The following example creates a [MySQLCommand](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
 Dim myCommand As New MySQLCommand()
 myCommand.CommandType = CommandType.Text
End Sub
```

C# example:

```
public void CreateMySQLCommand()
{
 MySqlCommand myCommand = new MySqlCommand();
 myCommand.CommandType = CommandType.Text;
}
```

### 29.2.3.1.2. Class MySQLCommand Constructor Form 2

Initializes a new instance of the [MySQLCommand](#) class with the text of the query.

**Parameters:** The text of the query.

When an instance of [MySQLCommand](#) is created, the following read/write properties are set to initial values.

| Properties                     | Initial Value           |
|--------------------------------|-------------------------|
| <a href="#">CommandText</a>    | <a href="#">cmdText</a> |
| <a href="#">CommandTimeout</a> | 0                       |
| <a href="#">CommandType</a>    | CommandType.Text        |
| <a href="#">Connection</a>     | Null                    |

You can change the value for any of these properties through a separate call to the property.

### Examples

The following example creates a [MySQLCommand](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
 Dim sql as String = "SELECT * FROM mytable"
 Dim myCommand As New MySQLCommand(sql)
 myCommand.CommandType = CommandType.Text
End Sub
```

C# example:

```
public void CreateMySQLCommand()
{
 string sql = "SELECT * FROM mytable";
 MySqlCommand myCommand = new MySqlCommand(sql);
 myCommand.CommandType = CommandType.Text;
}
```

### 29.2.3.1.3. Class MySQLCommand Constructor Form 3

Initializes a new instance of the [MySQLCommand](#) class with the text of the query and a [MySQLConnection](#).

**Parameters:** The text of the query.

**Parameters:** A [MySQLConnection](#) that represents the connection to an instance of SQL Server.

When an instance of [MySQLCommand](#) is created, the following read/write properties are set to initial values.

| Properties                     | Initial Value                    |
|--------------------------------|----------------------------------|
| <a href="#">CommandText</a>    | <a href="#">cmdText</a>          |
| <a href="#">CommandTimeout</a> | 0                                |
| <a href="#">CommandType</a>    | <a href="#">CommandType.Text</a> |
| <a href="#">Connection</a>     | <a href="#">connection</a>       |

You can change the value for any of these properties through a separate call to the property.

### Examples

The following example creates a [MySQLCommand](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
 Dim conn as new MySqlConnection("server=myServer")
 Dim sql as String = "SELECT * FROM mytable"
 Dim myCommand As New MySQLCommand(sql, conn)
 myCommand.CommandType = CommandType.Text
End Sub
```

C# example:

```
public void CreateMySQLCommand()
{
 MySqlConnection conn = new MySqlConnection("server=myserver")
 string sql = "SELECT * FROM mytable";
 MySQLCommand myCommand = new MySQLCommand(sql, conn);
 myCommand.CommandType = CommandType.Text;
}
```

#### 29.2.3.1.4. Class MySQLCommand Constructor Form 4

Initializes a new instance of the [MySQLCommand](#) class with the text of the query, a [MySQLConnection](#), and the [MySQLTransaction](#).

**Parameters:** The text of the query.

**Parameters:** A [MySQLConnection](#) that represents the connection to an instance of SQL Server.

**Parameters:** The [MySQLTransaction](#) in which the [MySQLCommand](#) executes.

When an instance of [MySQLCommand](#) is created, the following read/write properties are set to initial values.

| Properties                     | Initial Value                    |
|--------------------------------|----------------------------------|
| <a href="#">CommandText</a>    | <a href="#">cmdText</a>          |
| <a href="#">CommandTimeout</a> | 0                                |
| <a href="#">CommandType</a>    | <a href="#">CommandType.Text</a> |
| <a href="#">Connection</a>     | <a href="#">connection</a>       |

You can change the value for any of these properties through a separate call to the property.

### Examples

The following example creates a [MySQLCommand](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
 Dim conn as new MySqlConnection("server=myServer")
 conn.Open();
 Dim txn as MySQLTransaction = conn.BeginTransaction()
```

```
Dim sql as String = "SELECT * FROM mytable"
Dim myCommand As New MySqlCommand(sql, conn, txn)
myCommand.CommandType = CommandType.Text
End Sub
```

C# example:

```
public void CreateMySqlCommand()
{
 MySqlConnection conn = new MySqlConnection("server=myserver")
 conn.Open();
 MySqlTransaction txn = conn.BeginTransaction();
 string sql = "SELECT * FROM mytable";
 MySqlCommand myCommand = new MySqlCommand(sql, conn, txn);
 myCommand.CommandType = CommandType.Text;
}
```

### 29.2.3.1.5. ExecuteNonQuery

Executes a SQL statement against the connection and returns the number of rows affected.

**Returns:** Number of rows affected

You can use `ExecuteNonQuery` to perform any type of database operation, however any resultsets returned will not be available. Any output parameters used in calling a stored procedure will be populated with data and can be retrieved after execution is complete. For UPDATE, INSERT, and DELETE statements, the return value is the number of rows affected by the command. For all other types of statements, the return value is -1.

#### Examples

The following example creates a `MySqlCommand` and then executes it using `ExecuteNonQuery`. The example is passed a string that is a SQL statement (such as UPDATE, INSERT, or DELETE) and a string to use to connect to the data source.

Visual Basic example:

```
Public Sub CreateMySqlCommand(myExecuteQuery As String, myConnection As MySqlConnection)
 Dim myCommand As New MySqlCommand(myExecuteQuery, myConnection)
 myCommand.Connection.Open()
 myCommand.ExecuteNonQuery()
 myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySqlCommand(string myExecuteQuery, MySqlConnection myConnection)
{
 MySqlCommand myCommand = new MySqlCommand(myExecuteQuery, myConnection);
 myCommand.Connection.Open();
 myCommand.ExecuteNonQuery();
 myConnection.Close();
}
```

### 29.2.3.1.6. ExecuteReader1

Sends the `CommandText` to the `MySqlConnection`, and builds a `MySqlDataReader` using one of the `CommandBehavior` values.

**Parameters:** One of the `CommandBehavior` values.

When the `CommandType` property is set to `StoredProcedure`, the `CommandText` property should be set to the name of the stored procedure. The command executes this stored procedure when you call `ExecuteReader`.

The `MySqlDataReader` supports a special mode that enables large binary values to be read efficiently. For more information, see the `SequentialAccess` setting for `CommandBehavior`.

While the `MySqlDataReader` is in use, the associated `MySqlConnection` is busy serving the `MySqlDataReader`. While in this state, no other operations can be performed on the `MySqlConnection` other than closing it. This is the case until the `MySqlDataReader.Close` method of the `MySqlDataReader` is called. If the `MySqlDataReader` is created with `CommandBehavior` set to `CloseConnection`, closing the `MySqlDataReader` closes the connection automatically.

#### Note

When calling `ExecuteReader` with the `SingleRow` behavior, you should be aware that using a `limit` clause in

your SQL will cause all rows (up to the limit given) to be retrieved by the client. The `MySqlDataReader.Read` method will still return false after the first row but pulling all rows of data into the client will have a performance impact. If the `limit` clause is not necessary, it should be avoided.

**Returns:** A `MySqlDataReader` object.

### 29.2.3.1.7. Using `ExecuteReader`

Sends the `CommandText` to the `MySqlConnection` and builds a `MySqlDataReader`.

**Returns:** A `MySqlDataReader` object.

When the `CommandType` property is set to `StoredProcedure`, the `CommandText` property should be set to the name of the stored procedure. The command executes this stored procedure when you call `ExecuteReader`.

While the `MySqlDataReader` is in use, the associated `MySqlConnection` is busy serving the `MySqlDataReader`. While in this state, no other operations can be performed on the `MySqlConnection` other than closing it. This is the case until the `MySqlDataReader.Close` method of the `MySqlDataReader` is called.

#### Examples

The following example creates a `MySqlCommand`, then executes it by passing a string that is a SQL `SELECT` statement, and a string to use to connect to the data source.

Visual Basic example:

```
Public Sub CreateMySqlDataReader(mySelectQuery As String, myConnection As MySqlConnection)
 Dim myCommand As New MySqlCommand(mySelectQuery, myConnection)
 myConnection.Open()
 Dim myReader As MySqlDataReader
 myReader = myCommand.ExecuteReader()
 Try
 While myReader.Read()
 Console.WriteLine(myReader.GetString(0))
 End While
 Finally
 myReader.Close()
 myConnection.Close()
 End Try
End Sub
```

C# example:

```
public void CreateMySqlDataReader(string mySelectQuery, MySqlConnection myConnection)
{
 MySqlCommand myCommand = new MySqlCommand(mySelectQuery, myConnection);
 myConnection.Open();
 MySqlDataReader myReader;
 myReader = myCommand.ExecuteReader();
 try
 {
 while(myReader.Read())
 {
 Console.WriteLine(myReader.GetString(0));
 }
 }
 finally
 {
 myReader.Close();
 myConnection.Close();
 }
}
```

### 29.2.3.1.8. Using `Prepare`

Creates a prepared version of the command on an instance of MySQL Server.

Prepared statements are only supported on MySQL version 4.1 and higher. Calling prepare while connected to earlier versions of MySQL will succeed but will execute the statement in the same way as unprepared.

#### Examples

The following example demonstrates the use of the `Prepare` method.

Visual Basic example:

```
public sub PrepareExample()
 Dim cmd as New MySqlCommand("INSERT INTO mytable VALUES (?val)", myConnection)
 cmd.Parameters.Add(" ?val", 10)
 cmd.Prepare()
end sub
```

```
cmd.ExecuteNonQuery()

cmd.Parameters(0).Value = 20
cmd.ExecuteNonQuery()
end sub
```

C# example:

```
private void PrepareExample()
{
 MySqlCommand cmd = new MySqlCommand("INSERT INTO mytable VALUES (?val)", myConnection);
 cmd.Parameters.Add("?val", 10);
 cmd.Prepare();
 cmd.ExecuteNonQuery();

 cmd.Parameters[0].Value = 20;
 cmd.ExecuteNonQuery();
}
```

### 29.2.3.1.9. ExecuteScalar

Executes the query, and returns the first column of the first row in the result set returned by the query. Extra columns or rows are ignored.

**Returns:** The first column of the first row in the result set, or a null reference if the result set is empty

Use the [ExecuteScalar](#) method to retrieve a single value (for example, an aggregate value) from a database. This requires less code than using the [ExecuteReader](#) method, and then performing the operations necessary to generate the single value using the data returned by a [MySqlDataReader](#)

A typical [ExecuteScalar](#) query can be formatted as in the following C# example:

C# example:

```
cmd.CommandText = "select count(*) from region";
Int32 count = (int32) cmd.ExecuteScalar();
```

#### Examples

The following example creates a [MySqlCommand](#) and then executes it using [ExecuteScalar](#). The example is passed a string that is a SQL statement that returns an aggregate result, and a string to use to connect to the data source.

Visual Basic example:

```
Public Sub CreateMySqlCommand(myScalarQuery As String, myConnection As MySqlConnection)
 Dim myCommand As New MySqlCommand(myScalarQuery, myConnection)
 myCommand.Connection.Open()
 myCommand.ExecuteScalar()
 myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySqlCommand(string myScalarQuery, MySqlConnection myConnection)
{
 MySqlCommand myCommand = new MySqlCommand(myScalarQuery, myConnection);
 myCommand.Connection.Open();
 myCommand.ExecuteScalar();
 myConnection.Close();
}
```

C++ example:

```
public:
 void CreateMySqlCommand(String* myScalarQuery, MySqlConnection* myConnection)
 {
 MySqlCommand* myCommand = new MySqlCommand(myScalarQuery, myConnection);
 myCommand->Connection->Open();
 myCommand->ExecuteScalar();
 myConnection->Close();
 }
```

### 29.2.3.1.10. CommandText

Gets or sets the SQL statement to execute at the data source.

**Value:** The SQL statement or stored procedure to execute. The default is an empty string.

When the `CommandType` property is set to `StoredProcedure`, the `CommandText` property should be set to the name of the stored procedure. The user may be required to use escape character syntax if the stored procedure name contains any special characters. The command executes this stored procedure when you call one of the `Execute` methods.

### Examples

The following example creates a `MySqlCommand` and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
 Dim myCommand As New MySqlCommand()
 myCommand.CommandText = "SELECT * FROM Mytable ORDER BY id"
 myCommand.CommandType = CommandType.Text
End Sub
```

C# example:

```
public void CreateMySQLCommand()
{
 MySqlCommand myCommand = new MySqlCommand();
 myCommand.CommandText = "SELECT * FROM mytable ORDER BY id";
 myCommand.CommandType = CommandType.Text;
}
```

#### 29.2.3.1.11. CommandTimeout

Gets or sets the wait time before terminating the attempt to execute a command and generating an error.

**Value:** The time (in seconds) to wait for the command to execute. The default is 0 seconds.

MySQL currently does not support any method of canceling a pending or executing operation. All commands issued against a MySQL server will execute until completion or until an exception occurs.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about `CommandTimeout` in the Knowledge Base article, [Why CommandTimeout is not Supported](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

#### 29.2.3.1.12. CommandType

Gets or sets a value indicating how the `CommandText` property is to be interpreted.

**Value:** One of the `System.Data.CommandType` values. The default is `Text`.

When you set the `CommandType` property to `StoredProcedure`, you should set the `CommandText` property to the name of the stored procedure. The command executes this stored procedure when you call one of the `Execute` methods.

### Examples

The following example creates a `MySqlCommand` and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
 Dim myCommand As New MySqlCommand()
 myCommand.CommandType = CommandType.Text
End Sub
```

C# example:

```
public void CreateMySQLCommand()
{
 MySqlCommand myCommand = new MySqlCommand();
 myCommand.CommandType = CommandType.Text;
}
```

#### 29.2.3.1.13. Connection

Gets or sets the [MySQLConnection](#) used by this instance of the [MySQLCommand](#).

**Value:** The connection to a data source. The default value is a null reference ([Nothing](#) in Visual Basic).

If you set [Connection](#) while a transaction is in progress and the [Transaction](#) property is not null, an [InvalidOperationException](#) is generated. If the [Transaction](#) property is not null and the transaction has already been committed or rolled back, [Transaction](#) is set to null.

### Examples

The following example creates a [MySQLCommand](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
 Dim mySelectQuery As String = "SELECT * FROM mytable ORDER BY id"
 Dim myConnectionString As String = "Persist Security Info=False;database=test;server=myServer"
 Dim myCommand As New MySQLCommand(mySelectQuery)
 myCommand.Connection = New MySQLConnection(myConnectionString)
 myCommand.CommandType = CommandType.Text
End Sub
```

C# example:

```
public void CreateMySQLCommand()
{
 string mySelectQuery = "SELECT * FROM mytable ORDER BY id";
 string myConnectionString = "Persist Security Info=False;database=test;server=myServer";
 MySQLCommand myCommand = new MySQLCommand(mySelectQuery);
 myCommand.Connection = new MySQLConnection(myConnectionString);
 myCommand.CommandType = CommandType.Text;
}
```

#### 29.2.3.1.14. IsPrepared

Returns true if the statement is prepared.

#### 29.2.3.1.15. Parameters

Get the [MySQLParameterCollection](#)

**Value:** The parameters of the SQL statement or stored procedure. The default is an empty collection.

Connector/Net does not support unnamed parameters. Every parameter added to the collection must have an associated name.

### Examples

The following example creates a [MySQLCommand](#) and displays its parameters. To accomplish this, the method is passed a [MySQLConnection](#), a query string that is a SQL [SELECT](#) statement, and an array of [MySQLParameter](#) objects.

Visual Basic example:

```
Public Sub CreateMySQLCommand(myConnection As MySQLConnection, _
mySelectQuery As String, myParamArray() As MySQLParameter)
 Dim myCommand As New MySQLCommand(mySelectQuery, myConnection)
 myCommand.CommandText = "SELECT id, name FROM mytable WHERE age=?age"
 myCommand.UpdatedRowSource = UpdateRowSource.Both
 myCommand.Parameters.Add(myParamArray)
 Dim j As Integer
 For j = 0 To myCommand.Parameters.Count - 1
 myCommand.Parameters.Add(myParamArray(j))
 Next j
 Dim myMessage As String = ""
 Dim i As Integer
 For i = 0 To myCommand.Parameters.Count - 1
 myMessage += myCommand.Parameters(i).ToString() & ControlChars.Cr
 Next i
 Console.WriteLine(myMessage)
End Sub
```

C# example:

```
public void CreateMySQLCommand(MySQLConnection myConnection, string mySelectQuery,
MySQLParameter[] myParamArray)
{
 MySQLCommand myCommand = new MySQLCommand(mySelectQuery, myConnection);
 myCommand.CommandText = "SELECT id, name FROM mytable WHERE age=?age";
 myCommand.Parameters.Add(myParamArray);
 for (int j=0; j<myParamArray.Length; j++)
```

```

{
 myCommand.Parameters.Add(myParamArray[j]) ;
}
string myMessage = "";
for (int i = 0; i < myCommand.Parameters.Count; i++)
{
 myMessage += myCommand.Parameters[i].ToString() + "\n";
}
MessageBox.Show(myMessage);
}

```

### 29.2.3.1.16. Transaction

Gets or sets the [MySqlCommandTransaction](#) within which the [MySqlCommand](#) executes.

**Value:** The [MySqlCommandTransaction](#). The default value is a null reference ([Nothing](#) in Visual Basic).

You cannot set the [Transaction](#) property if it is already set to a specific value, and the command is in the process of executing. If you set the transaction property to a [MySqlCommandTransaction](#) object that is not connected to the same [MySqlConnection](#) as the [MySqlCommand](#) object, an exception will be thrown the next time you attempt to execute a statement.

### 29.2.3.1.17. UpdatedRowSource

Gets or sets how command results are applied to the [DataRow](#) when used by the [System.Data.Common.DbDataAdapter.Update](#) method of the [System.Data.Common.DbDataAdapter](#).

**Value:** One of the [UpdateRowSource](#) values.

The default [System.Data.UpdateRowSource](#) value is [Both](#) unless the command is automatically generated (as in the case of the [MySqlCommandBuilder](#)), in which case the default is [None](#).

## 29.2.3.2. Using MySqlCommandBuilder

Automatically generates single-table commands used to reconcile changes made to a [DataSet](#) with the associated MySQL database. This class cannot be inherited.

The [MySqlDataAdapter](#) does not automatically generate the SQL statements required to reconcile changes made to a [System.Data.DataSet](#) with the associated instance of MySQL. However, you can create a [MySqlCommandBuilder](#) object to automatically generate SQL statements for single-table updates if you set the [MySqlDataAdapter.SelectCommand](#) property of the [MySqlDataAdapter](#). Then, any additional SQL statements that you do not set are generated by the [MySqlCommandBuilder](#).

The [MySqlCommandBuilder](#) registers itself as a listener for [MySqlDataAdapter.OnRowUpdating](#) events whenever you set the [DataAdapter](#) property. You can only associate one [MySqlDataAdapter](#) or [MySqlCommandBuilder](#) object with each other at one time.

To generate INSERT, UPDATE, or DELETE statements, the [MySqlCommandBuilder](#) uses the [SelectCommand](#) property to retrieve a required set of metadata automatically. If you change the [SelectCommand](#) after the metadata has been retrieved (for example, after the first update), you should call the [RefreshSchema](#) method to update the metadata.

The [SelectCommand](#) must also return at least one primary key or unique column. If none are present, an [InvalidOperationException](#) exception is generated, and the commands are not generated.

When using [MySqlCommandBuilder](#) and [INSERT](#) you should set the [ReturnGeneratedIdentifiers](#) property to [true](#) to ensure that [AUTO\\_INCREMENT](#) fields in MySQL tables return the automatically generated value.

The [MySqlCommandBuilder](#) also uses the [MySqlCommand.Connection](#), [MySqlCommand.CommandTimeout](#), and [MySqlCommand.Transaction](#) properties referenced by the [SelectCommand](#). The user should call [RefreshSchema](#) if any of these properties are modified, or if the [SelectCommand](#) itself is replaced. Otherwise the [MySqlDataAdapter.InsertCommand](#), [MySqlDataAdapter.UpdateCommand](#), and [MySqlDataAdapter.DeleteCommand](#) properties retain their previous values.

If you call [Dispose](#), the [MySqlCommandBuilder](#) is disassociated from the [MySqlDataAdapter](#), and the generated commands are no longer used.

#### Note

Caution must be used when using [MySqlCommandBuilder](#) on MySQL 4.0 systems. With MySQL 4.0, database/schema information is not provided to the connector for a query. This means that a query that pulls columns from two identically named tables in two or more different databases will not cause an exception to be thrown but will not work correctly. Even more dangerous is the situation where your select statement references database X but is executed in

database Y and both databases have tables with similar layouts. This situation can cause unwanted changes or deletes. This note does not apply to MySQL versions 4.1 and later.

### Examples

The following example uses the `MySqlCommand`, along `MySqlDataAdapter` and `MySqlConnection`, to select rows from a data source. The example is passed an initialized `System.Data.DataSet`, a connection string, a query string that is a SQL `SELECT` statement, and a string that is the name of the database table. The example then creates a `MySqlCommandBuilder`.

Visual Basic example:

```
Public Shared Function SelectRows(myConnection As String, mySelectQuery As String, myTableName As String) As DataSet
 Dim myConn As New MySqlConnection(myConnection)
 Dim myDataAdapter As New MySqlDataAdapter()
 myDataAdapter.SelectCommand = New MySqlCommand(mySelectQuery, myConn)
 Dim cb As SqlCommandBuilder = New SqlCommandBuilder(myDataAdapter)
 myConn.Open()
 Dim ds As DataSet = New DataSet
 myDataAdapter.Fill(ds, myTableName)
 ' Code to modify data in DataSet here
 ' Without the MySqlCommandBuilder this line would fail.
 myDataAdapter.Update(ds, myTableName)
 myConn.Close()
End Function 'SelectRows
```

C# example:

```
public static DataSet SelectRows(string myConnection, string mySelectQuery, string myTableName)
{
 MySqlConnection myConn = new MySqlConnection(myConnection);
 MySqlDataAdapter myDataAdapter = new MySqlDataAdapter();
 myDataAdapter.SelectCommand = new MySqlCommand(mySelectQuery, myConn);
 MySqlCommandBuilder cb = new MySqlCommandBuilder(myDataAdapter);
 myConn.Open();
 DataSet ds = new DataSet();
 myDataAdapter.Fill(ds, myTableName);
 //code to modify data in DataSet here
 //Without the MySqlCommandBuilder this line would fail
 myDataAdapter.Update(ds, myTableName);
 myConn.Close();
 return ds;
}
```

#### 29.2.3.2.1. Class MySqlCommandBuilder Constructor

Initializes a new instance of the `MySqlCommandBuilder` class.

#### 29.2.3.2.2. Class MySqlCommandBuilder Constructor Form 1

Initializes a new instance of the `MySqlCommandBuilder` class and sets the last one wins property.

**Parameters:** False to generate change protection code. True otherwise.

The `lastOneWins` parameter indicates whether SQL code should be included with the generated DELETE and UPDATE commands that checks the underlying data for changes. If `lastOneWins` is true then this code is not included and data records could be overwritten in a multi-user or multi-threaded environments. Setting `lastOneWins` to false will include this check which will cause a concurrency exception to be thrown if the underlying data record has changed without our knowledge.

#### 29.2.3.2.3. Class MySqlCommandBuilder Constructor Form 2

Initializes a new instance of the `MySqlCommandBuilder` class with the associated `MySqlDataAdapter` object.

**Parameters:** The `MySqlDataAdapter` to use.

The `MySqlCommandBuilder` registers itself as a listener for `MySqlDataAdapter.RowUpdating` events that are generated by the `MySqlDataAdapter` specified in this property.

When you create a new instance `MySqlCommandBuilder`, any existing `MySqlCommandBuilder` associated with this `MySqlDataAdapter` is released.

#### 29.2.3.2.4. Class MySqlCommandBuilder Constructor Form 3

Initializes a new instance of the `MySqlCommandBuilder` class with the associated `MySqlDataAdapter` object.

**Parameters:** The `MySqlDataAdapter` to use.

**Parameters:** False to generate change protection code. True otherwise.

The `MySqlCommandBuilder` registers itself as a listener for `MySqlDataAdapter.RowUpdating` events that are generated by the `MySqlDataAdapter` specified in this property.

When you create a new instance `MySqlCommandBuilder`, any existing `MySqlCommandBuilder` associated with this `MySqlDataAdapter` is released.

The `lastOneWins` parameter indicates whether SQL code should be included with the generated DELETE and UPDATE commands that checks the underlying data for changes. If `lastOneWins` is true then this code is not included and data records could be overwritten in a multi-user or multi-threaded environments. Setting `lastOneWins` to false will include this check which will cause a concurrency exception to be thrown if the underlying data record has changed without our knowledge.

#### 29.2.3.2.5. DataAdapter

Gets or sets a `MySqlDataAdapter` object for which SQL statements are automatically generated.

**Value:** A `MySqlDataAdapter` object.

The `MySqlCommandBuilder` registers itself as a listener for `MySqlDataAdapter.RowUpdating` events that are generated by the `MySqlDataAdapter` specified in this property.

When you create a new instance `MySqlCommandBuilder`, any existing `MySqlCommandBuilder` associated with this `MySqlDataAdapter` is released.

#### 29.2.3.2.6. QuotePrefix

Gets or sets the beginning character or characters to use when specifying MySQL database objects (for example, tables or columns) whose names contain characters such as spaces or reserved tokens.

**Value:** The beginning character or characters to use. The default value is `.

Database objects in MySQL can contain special characters such as spaces that would make normal SQL strings impossible to correctly parse. Use of the `QuotePrefix` and the `QuoteSuffix` properties allows the `MySqlCommandBuilder` to build SQL statements that handle this situation.

#### 29.2.3.2.7. QuoteSuffix

Gets or sets the beginning character or characters to use when specifying MySQL database objects (for example, tables or columns) whose names contain characters such as spaces or reserved tokens.

**Value:** The beginning character or characters to use. The default value is `.

Database objects in MySQL can contain special characters such as spaces that would make normal SQL strings impossible to correctly parse. Use of the `QuotePrefix` and the `QuoteSuffix` properties allows the `MySqlCommandBuilder` to build SQL statements that handle this situation.

#### 29.2.3.2.8. DeriveParameters

#### 29.2.3.2.9. GetDeleteCommand

Gets the automatically generated `MySqlCommand` object required to perform deletions on the database.

**Returns:** The `MySqlCommand` object generated to handle delete operations.

An application can use the `GetDeleteCommand` method for informational or troubleshooting purposes because it returns the `MySqlCommand` object to be executed.

You can also use `GetDeleteCommand` as the basis of a modified command. For example, you might call `GetDeleteCommand` and modify the `MySqlCommand.CommandTimeout` value, and then explicitly set that on the `MySqlDataAdapter`.

After the SQL statement is first generated, the application must explicitly call `RefreshSchema` if it changes the statement in any way. Otherwise, the `GetDeleteCommand` will be still be using information from the previous statement, which might not be correct. The SQL statements are first generated either when the application calls `System.Data.Common.DataAdapter.Update` or `GetDeleteCommand`.

#### 29.2.3.2.10. GetInsertCommand

Gets the automatically generated `MySqlCommand` object required to perform insertions on the database.

**Returns:** The `MySqlCommand` object generated to handle insert operations.

An application can use the `GetInsertCommand` method for informational or troubleshooting purposes because it returns the `MySqlCommand` object to be executed.

You can also use the `GetInsertCommand` as the basis of a modified command. For example, you might call `GetInsertCommand` and modify the `MySqlCommand.CommandTimeout` value, and then explicitly set that on the `MySqlDataAdapter`.

After the SQL statement is first generated, the application must explicitly call `RefreshSchema` if it changes the statement in any way. Otherwise, the `GetInsertCommand` will be still be using information from the previous statement, which might not be correct. The SQL statements are first generated either when the application calls `System.Data.Common.DataAdapter.Update` or `GetInsertCommand`.

### 29.2.3.2.11. GetUpdateCommand

Gets the automatically generated `MySqlCommand` object required to perform updates on the database.

**Returns:** The `MySqlCommand` object generated to handle update operations.

An application can use the `GetUpdateCommand` method for informational or troubleshooting purposes because it returns the `MySqlCommand` object to be executed.

You can also use `GetUpdateCommand` as the basis of a modified command. For example, you might call `GetUpdateCommand` and modify the `MySqlCommand.CommandTimeout` value, and then explicitly set that on the `MySqlDataAdapter`.

After the SQL statement is first generated, the application must explicitly call `RefreshSchema` if it changes the statement in any way. Otherwise, the `GetUpdateCommand` will be still be using information from the previous statement, which might not be correct. The SQL statements are first generated either when the application calls `System.Data.Common.DataAdapter.Update` or `GetUpdateCommand`.

### 29.2.3.2.12. RefreshSchema

Refreshes the database schema information used to generate INSERT, UPDATE, or DELETE statements.

An application should call `RefreshSchema` whenever the `SELECT` statement associated with the `MySqlCommandBuilder` changes.

An application should call `RefreshSchema` whenever the `MySqlDataAdapter.SelectCommand` value of the `MySqlDataAdapter` changes.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information on this topic in the Knowledge Base article, [Understanding MySqlCommandBuilder and the LastOneWins Setting](#). For information about subscribing to MySQL Enterprise see <http://www.mysql.com/products/enterprise/advisors.html>.

### 29.2.3.3. Using MySqlConnection

Represents an open connection to a MySQL Server database. This class cannot be inherited.

A `MySqlConnection` object represents a session to a MySQL Server data source. When you create an instance of `MySqlConnection`, all properties are set to their initial values. For a list of these values, see the `MySqlConnection` constructor.

If the `MySqlConnection` goes out of scope, it is not closed. Therefore, you must explicitly close the connection by calling `MySqlConnection.Close` or `MySqlConnection.Dispose`.

#### Examples

The following example creates a `MySqlCommand` and a `MySqlConnection`. The `MySqlConnection` is opened and set as the `MySqlCommand.Connection` for the `MySqlCommand`. The example then calls `MySqlCommand.ExecuteNonQuery`, and closes the connection. To accomplish this, the `ExecuteNonQuery` is passed a connection string and a query string that is a SQL INSERT statement.

Visual Basic example:

```
Public Sub InsertRow(myConnectionString As String)
 ' If the connection string is null, use a default.
 If myConnectionString = "" Then
 myConnectionString = "Database=Test;Data Source=localhost;User Id=username;Password=pass"
 End If
 Dim myConnection As New MySqlConnection(myConnectionString)
```

```

Dim myInsertQuery As String = "INSERT INTO Orders (id, customerId, amount) Values(1001, 23, 30.66)"
Dim myCommand As New MySqlCommand(myInsertQuery)
myCommand.Connection = myConnection
myConnection.Open()
myCommand.ExecuteNonQuery()
myCommand.Connection.Close()
End Sub

```

C# example:

```

public void InsertRow(string myConnectionString)
{
 // If the connection string is null, use a default.
 if(myConnectionString == "")
 {
 myConnectionString = "Database=Test;Data Source=localhost;User Id=username;Password=pass";
 }
 MySqlConnection myConnection = new MySqlConnection(myConnectionString);
 string myInsertQuery = "INSERT INTO Orders (id, customerId, amount) Values(1001, 23, 30.66)";
 MySqlCommand myCommand = new MySqlCommand(myInsertQuery);
 myCommand.Connection = myConnection;
 myConnection.Open();
 myCommand.ExecuteNonQuery();
 myCommand.Connection.Close();
}

```

### 29.2.3.3.1. Class MySqlConnection Constructor (Default)

Initializes a new instance of the [MySqlConnection](#) class.

When a new instance of [MySqlConnection](#) is created, the read/write properties are set to the following initial values unless they are specifically set using their associated keywords in the [ConnectionString](#) property.

| Properties                        | Initial Value      |
|-----------------------------------|--------------------|
| <a href="#">ConnectionString</a>  | empty string ("" ) |
| <a href="#">ConnectionTimeout</a> | 15                 |
| <a href="#">Database</a>          | empty string ("" ) |
| <a href="#">DataSource</a>        | empty string ("" ) |
| <a href="#">ServerVersion</a>     | empty string ("" ) |

You can change the value for these properties only by using the [ConnectionString](#) property.

#### Examples

##### Overload methods for MySqlConnection

Initializes a new instance of the [MySqlConnection](#) class.

### 29.2.3.3.2. Class MySqlConnection Constructor Form 1

Initializes a new instance of the [MySqlConnection](#) class when given a string containing the connection string.

When a new instance of [MySqlConnection](#) is created, the read/write properties are set to the following initial values unless they are specifically set using their associated keywords in the [ConnectionString](#) property.

| Properties                        | Initial Value      |
|-----------------------------------|--------------------|
| <a href="#">ConnectionString</a>  | empty string ("" ) |
| <a href="#">ConnectionTimeout</a> | 15                 |
| <a href="#">Database</a>          | empty string ("" ) |
| <a href="#">DataSource</a>        | empty string ("" ) |
| <a href="#">ServerVersion</a>     | empty string ("" ) |

You can change the value for these properties only by using the [ConnectionString](#) property.

#### Examples

**Parameters:** The connection properties used to open the MySQL database.

### 29.2.3.3.3. ConnectionString

Gets or sets the string used to connect to a MySQL Server database.

The `ConnectionString` returned may not be exactly like what was originally set but will be identical in terms of keyword/value pairs. Security information will not be included unless the Persist Security Info value is set to true.

You can use the `ConnectionString` property to connect to a database. The following example illustrates a typical connection string.

```
"Persist Security Info=False;database=MyDB;»
server=MySqlServer;user id=myUser;Password=myPass"
```

The `ConnectionString` property can be set only when the connection is closed. Many of the connection string values have corresponding read-only properties. When the connection string is set, all of these properties are updated, except when an error is detected. In this case, none of the properties are updated. `MySQLConnection` properties return only those settings contained in the `ConnectionString`.

To connect to a local machine, specify "localhost" for the server. If you do not specify a server, localhost is assumed.

Resetting the `ConnectionString` on a closed connection resets all connection string values (and related properties) including the password. For example, if you set a connection string that includes "Database= MyDb", and then reset the connection string to "Data Source=myserver;User Id=myUser;Password=myPass", the `MySQLConnection.Database` property is no longer set to MyDb.

The connection string is parsed immediately after being set. If errors in syntax are found when parsing, a runtime exception, such as `ArgumentException`, is generated. Other errors can be found only when an attempt is made to open the connection.

The basic format of a connection string consists of a series of keyword/value pairs separated by semicolons. The equal sign (=) connects each keyword and its value. Additional notes on setting values for options:

- To include values that contain a semicolon, single-quote character, or double-quote character, the value must be enclosed in double quotes. If the value contains both a semicolon and a double-quote character, the value can be enclosed in single quotes. The single quote is also useful if the value begins with a double-quote character. Conversely, the double quote can be used if the value begins with a single quote. If the value contains both single-quote and double-quote characters, the quote character used to enclose the value must be doubled each time it occurs within the value.
- To include preceding or trailing spaces in the string value, the value must be enclosed in either single quotes or double quotes. Any leading or trailing spaces around integer, Boolean, or enumerated values are ignored, even if enclosed in quotes. However, spaces within a string literal keyword or value are preserved. Using .NET Framework version 1.1, single or double quotes may be used within a connection string without using delimiters (for example, Data Source= my'Server or Data Source= my"Server), unless a quote character is the first or last character in the value.
- To include an equal sign (=) in a keyword or value, it must be preceded by another equal sign. For example, in the hypothetical connection string

```
"key==word=value"
```

the keyword is "key=word" and the value is "value".

- If a specific keyword in a keyword= value pair occurs multiple times in a connection string, the last occurrence listed is used in the value set.
- Keywords are not case sensitive.

The following table lists the valid names for keyword values within the `ConnectionString`.

| Name                                                                                                                                                                    | Default   | Description                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Connect Timeout</code> , <code>Connection Timeout</code>                                                                                                          | 15        | The length of time (in seconds) to wait for a connection to the server before terminating the attempt and generating an error.                                                                                                                                                                                                                     |
| <code>Host</code> , <code>Server</code> , <code>Data Source</code> , <code>Data-Source</code> , <code>Address</code> , <code>Addr</code> , <code>Network Address</code> | localhost | The name or network address of the instance of MySQL to which to connect. Multiple hosts can be specified separated by &. This can be useful where multiple MySQL servers are configured for replication and you are not concerned about the precise server you are connecting to. No attempt is made by the provider to synchronize writes to the |

|                                   |        |                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   |        | database so care should be taken when using this option. In Unix environment with Mono, this can be a fully qualified path to MySQL socket filename. With this configuration, the Unix socket will be used instead of TCP/IP socket. Currently only a single socket name can be given so accessing MySQL in a replicated environment using Unix sockets is not currently supported. |
| Ignore Prepare                    | true   | When true, instructs the provider to ignore any calls to <code>MySqlCommand.Prepare()</code> . This option is provided to prevent issues with corruption of the statements when use with server side prepared statements. If you want to use server-side prepare statements, set this option to false. This option was added in Connector/NET 5.0.3 and Connector/NET 1.0.9.        |
| Port                              | 3306   | The port MySQL is using to listen for connections. Specify -1 for this value to use a named pipe connection (Windows only). This value is ignored if Unix socket is used.                                                                                                                                                                                                           |
| Protocol                          | socket | Specifies the type of connection to make to the server. Values can be: socket or tcp for a socket connection pipe for a named pipe connection unix for a Unix socket connection memory to use MySQL shared memory                                                                                                                                                                   |
| CharSet, Character Set            |        | Specifies the character set that should be used to encode all queries sent to the server. Resultsets are still returned in the character set of the data returned.                                                                                                                                                                                                                  |
| Logging                           | false  | When true, various pieces of information is output to any configured TraceListeners.                                                                                                                                                                                                                                                                                                |
| Allow Batch                       | true   | When true, multiple SQL statements can be sent with one command execution. -Note- Starting with MySQL 4.1.1, batch statements should be separated by the server-defined separator character. Commands sent to earlier versions of MySQL should be separated with ';'.                                                                                                               |
| Encrypt                           | false  | For Connector/NET 5.0.3 and later, when true, SSL encryption is used for all data sent between the client and server if the server has a certificate installed. Recognized values are true, false, yes, and no. In versions before 5.0.3, this option had no effect.                                                                                                                |
| Initial Catalog, Database         | mysql  | The name of the database to use intially                                                                                                                                                                                                                                                                                                                                            |
| Password, pwd                     |        | The password for the MySQL account being used.                                                                                                                                                                                                                                                                                                                                      |
| Persist Security Info             | false  | When set to false or no (strongly recommended), security-sensitive information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state. Re-setting the connection string resets all connection string values including the password. Recognized values are true, false, yes, and no.                           |
| User Id, Username, Uid, User name |        | The MySQL login account being used.                                                                                                                                                                                                                                                                                                                                                 |
| Shared Memory Name                | MYSQL  | The name of the shared memory object to use for communication if the connection protocol is set to memory.                                                                                                                                                                                                                                                                          |
| Allow Zero Datetime               | false  | True to have <code>MySqlDataReader.GetValue()</code> return a <code>MySqlDateTime</code> for date or datetime columns that have illegal values. False will cause a <code>System.DateTime</code> object to be returned for legal values and an exception will be thrown for illegal values.                                                                                          |
| Convert Zero Datetime             | false  | True to have <code>MySqlDataReader.GetValue()</code> and <code>MySqlDataReader.GetDateTime()</code> return <code>DateTime.MinValue</code> for date or datetime columns that have illegal values.                                                                                                                                                                                    |
| Old Syntax, OldSyntax             | false  | Allows use of '@' symbol as a parameter marker. See <code>MySqlCommand</code> for more info. This is for compatibility only. All future code should be written to use the new '?' parameter marker.                                                                                                                                                                                 |
| Pipe Name, Pipe                   | mysql  | When set to the name of a named pipe, the <code>MySqlConnection</code> will attempt to connect to MySQL on that named pipe. This settings only applies to the Windows platform.                                                                                                                                                                                                     |
| Procedure Cache                   | 25     | Sets the size of the stored procedure cache. By default, Connector/NET will store the metadata (input/output datatypes) about the last 25 stored procedures used. To disable the stored procedure cache, set the value to zero (0). This option was added in Connector/NET 5.0.2 and Connector/NET 1.0.9.                                                                           |
| Use Procedure Bodies              | true   | Setting this option to false indicates that the user connecting to the                                                                                                                                                                                                                                                                                                              |

|                                      |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------|--|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                      |  | database does not have the <code>SELECT</code> privileges for the <code>mysql.proc</code> (stored procedures) table. When to set to <code>false</code> , Connector/NET will not rely on this information being available when the procedure is called. Because Connector/NET will be unable to determine this information, you should explicitly set the types of the all the parameters before the call and the parameters should be added to the command in the exact same order as they appear in the procedure definition. This option was added in Connector/NET 5.0.4 and Connector/NET 1.0.10. |
| <code>default command timeout</code> |  | Sets the default value of the command timeout to be used. This does not supercede the individual command timeout property on an individual command object. If you set the command timeout property, that will be used. This option was added in Connector/NET 5.1.4                                                                                                                                                                                                                                                                                                                                   |

The following table lists the valid names for connection pooling values within the `ConnectionString`. For more information about connection pooling, see Connection Pooling for the MySQL Data Provider.

| Name                                                                                 | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Connection Lifetime</code>                                                     | 0       | When a connection is returned to the pool, its creation time is compared with the current time, and the connection is destroyed if that time span (in seconds) exceeds the value specified by <code>Connection Lifetime</code> . This is useful in clustered configurations to force load balancing between a running server and a server just brought online. A value of zero (0) causes pooled connections to have the maximum connection timeout. |
| <code>Max Pool Size</code>                                                           | 100     | The maximum number of connections allowed in the pool.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>Min Pool Size</code>                                                           | 0       | The minimum number of connections allowed in the pool.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>Pooling</code>                                                                 | true    | When <code>true</code> , the <code>MySqlConnection</code> object is drawn from the appropriate pool, or if necessary, is created and added to the appropriate pool. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> .                                                                                                                                                                          |
| <code>Reset Pooled Connections, ResetConnections, ResetPooledConnections</code>      | true    | Specifies whether a ping and a reset should be sent to the server before a pooled connection is returned. Not resetting will yield faster connection opens but also will not clear out session items such as temp tables.                                                                                                                                                                                                                            |
| <code>Cache Server Configuration, CacheServerConfiguration, CacheServerConfig</code> | false   | Specifies whether server variables should be updated when a pooled connection is returned. Turning this one will yeild faster opens but will also not catch any server changes made by other connections.                                                                                                                                                                                                                                            |

When setting keyword or connection pooling values that require a Boolean value, you can use 'yes' instead of 'true', and 'no' instead of 'false'.

### Note

The MySQL Data Provider uses the native socket protocol to communicate with MySQL. Therefore, it does not support the use of an ODBC data source name (DSN) when connecting to MySQL because it does not add an ODBC layer.

### Caution

In this release, the application should use caution when constructing a connection string based on user input (for example when retrieving user ID and password information from a dialog box, and appending it to the connection string). The application should ensure that a user cannot embed extra connection string parameters in these values (for example, entering a password as "validpassword;database=somedb" in an attempt to attach to a different database).

### Examples

The following example creates a `MySqlConnection` and sets some of its properties

Visual Basic example:

```
Public Sub CreateConnection()
 Dim myConnection As New MySqlConnection()
 myConnection.ConnectionString = "Persist Security Info=False;database=myDB;server=myHost;Connect Timeout=30;user i
 myConnection.Open()
End Sub 'CreateConnection
```

C# example:

```
public void CreateConnection()
{
 MySqlConnection myConnection = new MySqlConnection();
 myConnection.ConnectionString = "Persist Security Info=False;database=myDB;server=myHost;Connect Timeout=30;user id=...";
 myConnection.Open();
}
```

### Examples

The following example creates a [MySqlConnection](#) in Unix environment with Mono installed. MySQL socket filename used in this example is `"/var/lib/mysql/mysql.sock"`. The actual filename depends on your MySQL configuration.

Visual Basic example:

```
Public Sub CreateConnection()
 Dim myConnection As New MySqlConnection()
 myConnection.ConnectionString = "database=myDB;server=/var/lib/mysql/mysql.sock;user id=myUser; pwd=myPass"
 myConnection.Open()
End Sub 'CreateConnection
```

C# example:

```
public void CreateConnection()
{
 MySqlConnection myConnection = new MySqlConnection();
 myConnection.ConnectionString = "database=myDB;server=/var/lib/mysql/mysql.sock;user id=myUser; pwd=myPass";
 myConnection.Open();
}
```

#### 29.2.3.3.4. Open

Opens a database connection with the property settings specified by the `ConnectionString`.

**Exception:** Cannot open a connection without specifying a data source or server.

**Exception:** A connection-level error occurred while opening the connection.

The [MySqlConnection](#) draws an open connection from the connection pool if one is available. Otherwise, it establishes a new connection to an instance of MySQL.

### Examples

The following example creates a [MySqlConnection](#), opens it, displays some of its properties, then closes the connection.

Visual Basic example:

```
Public Sub CreateMySQLConnection(myConnString As String)
 Dim myConnection As New MySqlConnection(myConnString)
 myConnection.Open()
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion _
 + ControlChars.Cr + "State: " + myConnection.State.ToString())
 myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLConnection(string myConnString)
{
 MySqlConnection myConnection = new MySqlConnection(myConnString);
 myConnection.Open();
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion +
 "\nState: " + myConnection.State.ToString());
 myConnection.Close();
}
```

#### 29.2.3.3.5. Database

Gets the name of the current database or the database to be used after a connection is opened.

**Returns:** The name of the current database or the name of the database to be used after a connection is opened. The default value is

an empty string.

The `Database` property does not update dynamically. If you change the current database using a SQL statement, then this property may reflect the wrong value. If you change the current database using the `ChangeDatabase` method, this property is updated to reflect the new database.

### Examples

The following example creates a `MySQLConnection` and displays some of its read-only properties.

Visual Basic example:

```
Public Sub CreateMySQLConnection()
 Dim myConnString As String = _
 "Persist Security Info=False;database=test;server=localhost;user id=joeuser;pwd=pass"
 Dim myConnection As New MySQLConnection(myConnString)
 myConnection.Open()
 MessageBox.Show("Server Version: " + myConnection.ServerVersion _
 + ControlChars.NewLine + "Database: " + myConnection.Database)
 myConnection.ChangeDatabase("test2")
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion _
 + ControlChars.NewLine + "Database: " + myConnection.Database)
 myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLConnection()
{
 string myConnString =
 "Persist Security Info=False;database=test;server=localhost;user id=joeuser;pwd=pass";
 MySQLConnection myConnection = new MySQLConnection(myConnString);
 myConnection.Open();
 MessageBox.Show("Server Version: " + myConnection.ServerVersion
 + "\nDatabase: " + myConnection.Database);
 myConnection.ChangeDatabase("test2");
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion
 + "\nDatabase: " + myConnection.Database);
 myConnection.Close();
}
```

### 29.2.3.3.6. State

Gets the current state of the connection.

**Returns:** A bitwise combination of the `System.Data.ConnectionState` values. The default is `Closed`.

The allowed state changes are:

- From `Closed` to `Open`, using the `Open` method of the connection object.
- From `Open` to `Closed`, using either the `Close` method or the `Dispose` method of the connection object.

### Examples

The following example creates a `MySQLConnection`, opens it, displays some of its properties, then closes the connection.

Visual Basic example:

```
Public Sub CreateMySQLConnection(myConnString As String)
 Dim myConnection As New MySQLConnection(myConnString)
 myConnection.Open()
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion _
 + ControlChars.Cr + "State: " + myConnection.State.ToString())
 myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLConnection(string myConnString)
{
 MySQLConnection myConnection = new MySQLConnection(myConnString);
 myConnection.Open();
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion +
 "\nState: " + myConnection.State.ToString());
 myConnection.Close();
}
```

### 29.2.3.3.7. ServerVersion

Gets a string containing the version of the MySQL server to which the client is connected.

**Returns:** The version of the instance of MySQL.

**Exception:** The connection is closed.

#### Examples

The following example creates a [MySQLConnection](#), opens it, displays some of its properties, then closes the connection.

Visual Basic example:

```
Public Sub CreateMySQLConnection(myConnString As String)
 Dim myConnection As New MySqlConnection(myConnString)
 myConnection.Open()
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion _
 + ControlChars.Cr + "State: " + myConnection.State.ToString())
 myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLConnection(string myConnString)
{
 MySqlConnection myConnection = new MySqlConnection(myConnString);
 myConnection.Open();
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion +
 "\nState: " + myConnection.State.ToString());
 myConnection.Close();
}
```

### 29.2.3.3.8. Close

Closes the connection to the database. This is the preferred method of closing any open connection.

The [Close](#) method rolls back any pending transactions. It then releases the connection to the connection pool, or closes the connection if connection pooling is disabled.

An application can call [Close](#) more than one time. No exception is generated.

#### Examples

The following example creates a [MySQLConnection](#), opens it, displays some of its properties, then closes the connection.

Visual Basic example:

```
Public Sub CreateMySQLConnection(myConnString As String)
 Dim myConnection As New MySqlConnection(myConnString)
 myConnection.Open()
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion _
 + ControlChars.Cr + "State: " + myConnection.State.ToString())
 myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLConnection(string myConnString)
{
 MySqlConnection myConnection = new MySqlConnection(myConnString);
 myConnection.Open();
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion +
 "\nState: " + myConnection.State.ToString());
 myConnection.Close();
}
```

### 29.2.3.3.9. CreateCommand

Creates and returns a [MySQLCommand](#) object associated with the [MySQLConnection](#).

**Returns:** A `MySqlCommand` object.

### 29.2.3.3.10. BeginTransaction

Begins a database transaction.

**Returns:** An object representing the new transaction.

**Exception:** Parallel transactions are not supported.

This command is equivalent to the MySQL `BEGIN TRANSACTION` command.

You must explicitly commit or roll back the transaction using the `MySQLTransaction.Commit` or `MySQLTransaction.Rollback` method.

#### Note

If you do not specify an isolation level, the default isolation level is used. To specify an isolation level with the `BeginTransaction` method, use the overload that takes the `iso` parameter.

#### Examples

The following example creates a `MySQLConnection` and a `MySQLTransaction`. It also demonstrates how to use the `BeginTransaction`, a `MySQLTransaction.Commit`, and `MySQLTransaction.Rollback` methods.

Visual Basic example:

```
Public Sub RunTransaction(myConnString As String)
 Dim myConnection As New MySqlConnection(myConnString)
 myConnection.Open()

 Dim myCommand As MySqlCommand = myConnection.CreateCommand()
 Dim myTrans As MySQLTransaction

 ' Start a local transaction
 myTrans = myConnection.BeginTransaction()
 ' Must assign both transaction object and connection
 ' to Command object for a pending local transaction
 myCommand.Connection = myConnection
 myCommand.Transaction = myTrans

 Try
 myCommand.CommandText = "Insert into Test (id, desc) VALUES (100, 'Description')"
 myCommand.ExecuteNonQuery()
 myCommand.CommandText = "Insert into Test (id, desc) VALUES (101, 'Description')"
 myCommand.ExecuteNonQuery()
 myTrans.Commit()
 Console.WriteLine("Both records are written to database.")
 Catch ex As Exception
 Try
 myTrans.Rollback()
 Catch ex As MySQLException
 If Not myTrans.Connection Is Nothing Then
 Console.WriteLine("An exception of type " + ex.GetType().ToString() + _
 " was encountered while attempting to roll back the transaction.")
 End If
 End Try

 Console.WriteLine("An exception of type " + ex.GetType().ToString() + _
 "was encountered while inserting the data.")
 Console.WriteLine("Neither record was written to database.")
 Finally
 myConnection.Close()
 End Try
End Sub
```

C# example:

```
public void RunTransaction(string myConnString)
{
 MySqlConnection myConnection = new MySqlConnection(myConnString);
 myConnection.Open();
 MySqlCommand myCommand = myConnection.CreateCommand();
 MySQLTransaction myTrans;
 // Start a local transaction
 myTrans = myConnection.BeginTransaction();
 // Must assign both transaction object and connection
 // to Command object for a pending local transaction
 myCommand.Connection = myConnection;
 myCommand.Transaction = myTrans;
 try
 {
 myCommand.CommandText = "insert into Test (id, desc) VALUES (100, 'Description')";
 myCommand.ExecuteNonQuery();
 }
}
```

```

myCommand.CommandText = "insert into Test (id, desc) VALUES (101, 'Description')";
myCommand.ExecuteNonQuery();
myTrans.Commit();
Console.WriteLine("Both records are written to database.");
}
catch(Exception e)
{
 try
 {
 myTrans.Rollback();
 }
 catch (SqlException ex)
 {
 if (myTrans.Connection != null)
 {
 Console.WriteLine("An exception of type " + ex.GetType() +
 " was encountered while attempting to roll back the transaction.");
 }
 }

 Console.WriteLine("An exception of type " + e.GetType() +
 " was encountered while inserting the data.");
 Console.WriteLine("Neither record was written to database.");
}
finally
{
 myConnection.Close();
}
}

```

### 29.2.3.3.11. BeginTransaction1

Begins a database transaction with the specified isolation level.

**Parameters:** The isolation level under which the transaction should run.

**Returns:** An object representing the new transaction.

**Exception:** Parallel exceptions are not supported.

This command is equivalent to the MySQL BEGIN TRANSACTION command.

You must explicitly commit or roll back the transaction using the [MySQLTransaction.Commit](#) or [MySQLTransaction.Rollback](#) method.

#### Note

If you do not specify an isolation level, the default isolation level is used. To specify an isolation level with the [BeginTransaction](#) method, use the overload that takes the `iso` parameter.

#### Examples

The following example creates a [MySQLConnection](#) and a [MySQLTransaction](#). It also demonstrates how to use the [BeginTransaction](#), a [MySQLTransaction.Commit](#), and [MySQLTransaction.Rollback](#) methods.

Visual Basic example:

```

Public Sub RunTransaction(myConnString As String)
 Dim myConnection As New MySqlConnection(myConnString)
 myConnection.Open()

 Dim myCommand As MySqlCommand = myConnection.CreateCommand()
 Dim myTrans As MySQLTransaction

 ' Start a local transaction
 myTrans = myConnection.BeginTransaction()
 ' Must assign both transaction object and connection
 ' to Command object for a pending local transaction
 myCommand.Connection = myConnection
 myCommand.Transaction = myTrans

 Try
 myCommand.CommandText = "Insert into Test (id, desc) VALUES (100, 'Description')"
 myCommand.ExecuteNonQuery()
 myCommand.CommandText = "Insert into Test (id, desc) VALUES (101, 'Description')"
 myCommand.ExecuteNonQuery()
 myTrans.Commit()
 Console.WriteLine("Both records are written to database.")
 Catch e As Exception
 Try
 myTrans.Rollback()
 Catch ex As MySQLException
 If Not myTrans.Connection Is Nothing Then
 Console.WriteLine("An exception of type " + ex.GetType().ToString() + _
 " was encountered while attempting to roll back the transaction.")
 End If
 End Try
 End Try
End Sub

```

```

 End If
 End Try

 Console.WriteLine("An exception of type " + e.GetType().ToString() + _
 "was encountered while inserting the data.")
 Console.WriteLine("Neither record was written to database.")
Finally
 myConnection.Close()
End Try
End Sub

```

C# example:

```

public void RunTransaction(string myConnString)
{
 MySqlConnection myConnection = new MySqlConnection(myConnString);
 myConnection.Open();
 MySqlCommand myCommand = myConnection.CreateCommand();
 MySqlTransaction myTrans;
 // Start a local transaction
 myTrans = myConnection.BeginTransaction();
 // Must assign both transaction object and connection
 // to Command object for a pending local transaction
 myCommand.Connection = myConnection;
 myCommand.Transaction = myTrans;
 try
 {
 myCommand.CommandText = "insert into Test (id, desc) VALUES (100, 'Description')";
 myCommand.ExecuteNonQuery();
 myCommand.CommandText = "insert into Test (id, desc) VALUES (101, 'Description')";
 myCommand.ExecuteNonQuery();
 myTrans.Commit();
 Console.WriteLine("Both records are written to database.");
 }
 catch (Exception e)
 {
 try
 {
 myTrans.Rollback();
 }
 catch (SqlException ex)
 {
 if (myTrans.Connection != null)
 {
 Console.WriteLine("An exception of type " + ex.GetType() +
 " was encountered while attempting to roll back the transaction.");
 }
 }

 Console.WriteLine("An exception of type " + e.GetType() +
 " was encountered while inserting the data.");
 Console.WriteLine("Neither record was written to database.");
 }
 finally
 {
 myConnection.Close();
 }
}

```

### 29.2.3.3.12. ChangeDatabase

Changes the current database for an open MySqlConnection.

**Parameters:** The name of the database to use.

The value supplied in the `database` parameter must be a valid database name. The `database` parameter cannot contain a null value, an empty string, or a string with only blank characters.

When you are using connection pooling against MySQL, and you close the connection, it is returned to the connection pool. The next time the connection is retrieved from the pool, the reset connection request executes before the user performs any operations.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information on this subject in the Knowledge Base article, [Understanding and Using Connection Pooling](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. To subscribe see <http://www.mysql.com/products/enterprise/advisors.html>.

**Exception:** The database name is not valid.

**Exception:** The connection is not open.

**Exception:** Cannot change the database.

## Examples

The following example creates a [MySQLConnection](#) and displays some of its read-only properties.

Visual Basic example:

```
Public Sub CreateMySQLConnection()
 Dim myConnString As String = _
 "Persist Security Info=False;database=test;server=localhost;user id=joeuser;pwd=pass"
 Dim myConnection As New MySqlConnection(myConnString)
 myConnection.Open()
 MessageBox.Show("Server Version: " + myConnection.ServerVersion _
 + ControlChars.NewLine + "Database: " + myConnection.Database)
 myConnection.ChangeDatabase("test2")
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion _
 + ControlChars.NewLine + "Database: " + myConnection.Database)
 myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLConnection()
{
 string myConnString =
 "Persist Security Info=False;database=test;server=localhost;user id=joeuser;pwd=pass";
 MySqlConnection myConnection = new MySqlConnection(myConnString);
 myConnection.Open();
 MessageBox.Show("Server Version: " + myConnection.ServerVersion
 + "\nDatabase: " + myConnection.Database);
 myConnection.ChangeDatabase("test2");
 MessageBox.Show("ServerVersion: " + myConnection.ServerVersion
 + "\nDatabase: " + myConnection.Database);
 myConnection.Close();
}
```

### 29.2.3.3.13. StateChange

Occurs when the state of the connection changes.

The [StateChange](#) event fires whenever the [State](#) changes from closed to opened, or from opened to closed. [StateChange](#) fires immediately after the [MySQLConnection](#) transitions.

If an event handler throws an exception from within the [StateChange](#) event, the exception propagates to the caller of the [Open](#) or [Close](#) method.

The [StateChange](#) event is not raised unless you explicitly call [Close](#) or [Dispose](#).

The event handler receives an argument of type [System.Data.StateChangeEventArgs](#) containing data related to this event. The following [StateChangeEventArgs](#) properties provide information specific to this event.

| Property                                                       | Description                                                                                                           |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <a href="#">System.Data.StateChangeEventArgs.CurrentState</a>  | Gets the new state of the connection. The connection object will be in the new state already when the event is fired. |
| <a href="#">System.Data.StateChangeEventArgs.OriginalState</a> | Gets the original state of the connection.                                                                            |

### 29.2.3.3.14. InfoMessage

Occurs when MySQL returns warnings as a result of executing a command or query.

### 29.2.3.3.15. ConnectionTimeout

Gets the time to wait while trying to establish a connection before terminating the attempt and generating an error.

**Exception:** The value set is less than 0.

A value of 0 indicates no limit, and should be avoided in a [MySQLConnection.ConnectionString](#) because an attempt to connect will wait indefinitely.

## Examples

The following example creates a `MySqlConnection` and sets some of its properties in the connection string.

Visual Basic example:

```
Public Sub CreateSqlConnection()
 Dim myConnection As New MySqlConnection()
 myConnection.ConnectionString = "Persist Security Info=False;Username=user;Password=pass;database=test1;server=localhost"
 myConnection.Open()
End Sub
```

C# example:

```
public void CreateSqlConnection()
{
 MySqlConnection myConnection = new MySqlConnection();
 myConnection.ConnectionString = "Persist Security Info=False;Username=user;»
 Password=pass;database=test1;server=localhost;Connect Timeout=30";
 myConnection.Open();
}
```

### 29.2.3.4. Using `MySqlDataAdapter`

Represents a set of data commands and a database connection that are used to fill a data set and update a MySQL database. This class cannot be inherited.

The `MySQLDataAdapter`, serves as a bridge between a `System.Data.DataSet` and MySQL for retrieving and saving data. The `MySQLDataAdapter` provides this bridge by mapping `DbDataAdapter.Fill`, which changes the data in the `DataSet` to match the data in the data source, and `DbDataAdapter.Update`, which changes the data in the data source to match the data in the `DataSet`, using the appropriate SQL statements against the data source.

When the `MySQLDataAdapter` fills a `DataSet`, it will create the necessary tables and columns for the returned data if they do not already exist. However, primary key information will not be included in the implicitly created schema unless the `System.Data.MissingSchemaAction` property is set to `System.Data.MissingSchemaAction.AddWithKey`. You may also have the `MySQLDataAdapter` create the schema of the `DataSet`, including primary key information, before filling it with data using `System.Data.Common.DbDataAdapter.FillSchema`.

`MySQLDataAdapter` is used in conjunction with `MySqlConnection` and `MySqlCommand` to increase performance when connecting to a MySQL database.

The `MySQLDataAdapter` also includes the `MySqlCommand.SelectCommand`, `MySqlCommand.InsertCommand`, `MySqlCommand.DeleteCommand`, `MySqlCommand.UpdateCommand`, and `DataAdapter.TableMappings` properties to facilitate the loading and updating of data.

When an instance of `MySQLDataAdapter` is created, the read/write properties are set to initial values. For a list of these values, see the `MySQLDataAdapter` constructor.

#### Note

Please be aware that the `DataColumn` class in .NET 1.0 and 1.1 does not allow columns with type of `UInt16`, `UInt32`, or `UInt64` to be autoincrement columns. If you plan to use autoincrement columns with MySQL, you should consider using signed integer columns.

#### Examples

The following example creates a `MySqlCommand` and a `MySqlConnection`. The `MySqlConnection` is opened and set as the `MySqlCommand.Connection` for the `MySqlCommand`. The example then calls `MySqlCommand.ExecuteNonQuery`, and closes the connection. To accomplish this, the `ExecuteNonQuery` is passed a connection string and a query string that is a SQL INSERT statement.

Visual Basic example:

```
Public Function SelectRows(dataset As DataSet, connection As String, query As String) As DataSet
 Dim conn As New MySqlConnection(connection)
 Dim adapter As New MySqlDataAdapter()
 adapter.SelectCommand = new MySqlCommand(query, conn)
 adapter.Fill(dataset)
 Return dataset
End Function
```

C# example:

```
public DataSet SelectRows(DataSet dataset,string connection,string query)
{
 MySqlConnection conn = new MySqlConnection(connection);
```

```

MySQLDataAdapter adapter = new MySQLDataAdapter();
adapter.SelectCommand = new MySqlCommand(query, conn);
adapter.Fill(dataset);
return dataset;
}

```

### 29.2.3.4.1. Class MySQLDataAdapter Constructor

#### Overload methods for MySQLDataAdapter

Initializes a new instance of the MySQLDataAdapter class.

When an instance of [MySQLDataAdapter](#) is created, the following read/write properties are set to the following initial values.

| Properties                           | Initial Value                                    |
|--------------------------------------|--------------------------------------------------|
| <a href="#">MissingMappingAction</a> | <a href="#">MissingMappingAction.Passthrough</a> |
| <a href="#">MissingSchemaAction</a>  | <a href="#">MissingSchemaAction.Add</a>          |

You can change the value of any of these properties through a separate call to the property.

#### Examples

The following example creates a [MySQLDataAdapter](#) and sets some of its properties.

Visual Basic example:

```

Public Sub CreateSqlDataAdapter()
 Dim conn As MySqlConnection = New MySqlConnection("Data Source=localhost;" & _
 "database=test")
 Dim da As MySQLDataAdapter = New MySQLDataAdapter
 da.MissingSchemaAction = MissingSchemaAction.AddWithKey

 da.SelectCommand = New MySqlCommand("SELECT id, name FROM mytable", conn)
 da.InsertCommand = New MySqlCommand("INSERT INTO mytable (id, name) " & _
 "VALUES (?id, ?name)", conn)
 da.UpdateCommand = New MySqlCommand("UPDATE mytable SET id=?id, name=?name " & _
 "WHERE id=?oldId", conn)
 da.DeleteCommand = New MySqlCommand("DELETE FROM mytable WHERE id=?id", conn)
 da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
 da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")

 da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
 da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")
 da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
 da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
End Sub

```

C# example:

```

public static void CreateSqlDataAdapter()
{
 MySqlConnection conn = new MySqlConnection("Data Source=localhost;database=test");
 MySQLDataAdapter da = new MySQLDataAdapter();
 da.MissingSchemaAction = MissingSchemaAction.AddWithKey;

 da.SelectCommand = new MySqlCommand("SELECT id, name FROM mytable", conn);
 da.InsertCommand = new MySqlCommand("INSERT INTO mytable (id, name) " +
 "VALUES (?id, ?name)", conn);
 da.UpdateCommand = new MySqlCommand("UPDATE mytable SET id=?id, name=?name " +
 "WHERE id=?oldId", conn);
 da.DeleteCommand = new MySqlCommand("DELETE FROM mytable WHERE id=?id", conn);
 da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
 da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");

 da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
 da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");
 da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original;
 da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original;
}

```

### 29.2.3.4.2. Class MySQLDataAdapter Constructor Form 1

Initializes a new instance of the [MySQLDataAdapter](#) class with the specified [MySqlCommand](#) as the [SelectCommand](#) property.

**Parameters:** [MySqlCommand](#) that is a SQL [SELECT](#) statement or stored procedure and is set as the [SelectCommand](#) property of the [MySQLDataAdapter](#).

When an instance of [MySQLDataAdapter](#) is created, the following read/write properties are set to the following initial values.

| Properties                           | Initial Value                                    |
|--------------------------------------|--------------------------------------------------|
| <a href="#">MissingMappingAction</a> | <a href="#">MissingMappingAction.Passthrough</a> |
| <a href="#">MissingSchemaAction</a>  | <a href="#">MissingSchemaAction.Add</a>          |

You can change the value of any of these properties through a separate call to the property.

When [SelectCommand](#) (or any of the other command properties) is assigned to a previously created [MySQLCommand](#), the [MySQLCommand](#) is not cloned. The [SelectCommand](#) maintains a reference to the previously created [MySQLCommand](#) object.

### Examples

The following example creates a [MySQLDataAdapter](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateSqlDataAdapter()
 Dim conn As MySqlConnection = New MySqlConnection("Data Source=localhost;" & _
 "database=test")
 Dim cmd As new MySqlCommand("SELECT id, name FROM mytable", conn)
 Dim da As MySQLDataAdapter = New MySQLDataAdapter(cmd)
 da.MissingSchemaAction = MissingSchemaAction.AddWithKey

 da.InsertCommand = New MySqlCommand("INSERT INTO mytable (id, name) " & _
 "VALUES (?id, ?name)", conn)
 da.UpdateCommand = New MySqlCommand("UPDATE mytable SET id=?id, name=?name " & _
 "WHERE id=?oldId", conn)
 da.DeleteCommand = New MySqlCommand("DELETE FROM mytable WHERE id=?id", conn)
 da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
 da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")

 da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
 da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")
 da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
 da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
End Sub
```

C# example:

```
public static void CreateSqlDataAdapter()
{
 MySqlConnection conn = new MySqlConnection("Data Source=localhost;database=test");
 MySqlCommand cmd = new MySqlCommand("SELECT id, name FROM mytable", conn);
 MySQLDataAdapter da = new MySQLDataAdapter(cmd);
 da.MissingSchemaAction = MissingSchemaAction.AddWithKey;

 da.InsertCommand = new MySqlCommand("INSERT INTO mytable (id, name) " +
 "VALUES (?id, ?name)", conn);
 da.UpdateCommand = new MySqlCommand("UPDATE mytable SET id=?id, name=?name " +
 "WHERE id=?oldId", conn);
 da.DeleteCommand = new MySqlCommand("DELETE FROM mytable WHERE id=?id", conn);
 da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
 da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");

 da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
 da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");
 da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original;
 da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original;
}
```

### 29.2.3.4.3. Class [MySQLDataAdapter](#) Constructor Form 2

Initializes a new instance of the [MySQLDataAdapter](#) class with a [SelectCommand](#) and a [MySQLConnection](#) object.

**Parameters:** A [String](#) that is a SQL [SELECT](#) statement or stored procedure to be used by the [SelectCommand](#) property of the [MySQLDataAdapter](#).

**Parameters:** A [MySQLConnection](#) that represents the connection.

This implementation of the [MySQLDataAdapter](#) opens and closes a [MySQLConnection](#) if it is not already open. This can be useful in an application that must call the [DbDataAdapter.Fill](#) method for two or more [MySQLDataAdapter](#) objects. If the [MySQLConnection](#) is already open, you must explicitly call [MySQLConnection.Close](#) or [MySQLConnection.Dispose](#) to close it.

When an instance of [MySQLDataAdapter](#) is created, the following read/write properties are set to the following initial values.

| Properties                           | Initial Value                                    |
|--------------------------------------|--------------------------------------------------|
| <a href="#">MissingMappingAction</a> | <a href="#">MissingMappingAction.Passthrough</a> |
| <a href="#">MissingSchemaAction</a>  | <a href="#">MissingSchemaAction.Add</a>          |

You can change the value of any of these properties through a separate call to the property.

### Examples

The following example creates a [MySqlDataAdapter](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateSqlDataAdapter()
 Dim conn As MySqlConnection = New MySqlConnection("Data Source=localhost;" & _
 "database=test")
 Dim da As MySqlDataAdapter = New MySqlDataAdapter("SELECT id, name FROM mytable", conn)
 da.MissingSchemaAction = MissingSchemaAction.AddWithKey

 da.InsertCommand = New MySqlCommand("INSERT INTO mytable (id, name) " & _
 "VALUES (?id, ?name)", conn)
 da.UpdateCommand = New MySqlCommand("UPDATE mytable SET id=?id, name=?name " & _
 "WHERE id=?oldId", conn)
 da.DeleteCommand = New MySqlCommand("DELETE FROM mytable WHERE id=?id", conn)
 da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
 da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")

 da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
 da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")
 da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
 da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
End Sub
```

C# example:

```
public static void CreateSqlDataAdapter()
{
 MySqlConnection conn = new MySqlConnection("Data Source=localhost;database=test");
 MySqlDataAdapter da = new MySqlDataAdapter("SELECT id, name FROM mytable", conn);
 da.MissingSchemaAction = MissingSchemaAction.AddWithKey;

 da.InsertCommand = new MySqlCommand("INSERT INTO mytable (id, name) " +
 "VALUES (?id, ?name)", conn);
 da.UpdateCommand = new MySqlCommand("UPDATE mytable SET id=?id, name=?name " +
 "WHERE id=?oldId", conn);
 da.DeleteCommand = new MySqlCommand("DELETE FROM mytable WHERE id=?id", conn);
 da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
 da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");

 da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
 da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");
 da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original;
 da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original;
}
```

#### 29.2.3.4.4. Class [MySqlDataAdapter](#) Constructor Form 3

Initializes a new instance of the [MySqlDataAdapter](#) class with a [SelectCommand](#) and a connection string.

**Parameters:** A [string](#) that is a SQL [SELECT](#) statement or stored procedure to be used by the [SelectCommand](#) property of the [MySqlDataAdapter](#).

**Parameters:** The connection string

When an instance of [MySqlDataAdapter](#) is created, the following read/write properties are set to the following initial values.

| Properties                           | Initial Value                                    |
|--------------------------------------|--------------------------------------------------|
| <a href="#">MissingMappingAction</a> | <a href="#">MissingMappingAction.Passthrough</a> |
| <a href="#">MissingSchemaAction</a>  | <a href="#">MissingSchemaAction.Add</a>          |

You can change the value of any of these properties through a separate call to the property.

### Examples

The following example creates a [MySqlDataAdapter](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateSqlDataAdapter()
 Dim da As MySqlDataAdapter = New MySqlDataAdapter("SELECT id, name FROM mytable", "Data Source=localhost;database=test")
 Dim conn As MySqlConnection = da.SelectCommand.Connection
 da.MissingSchemaAction = MissingSchemaAction.AddWithKey

 da.InsertCommand = New MySqlCommand("INSERT INTO mytable (id, name) " & _
 "VALUES (?id, ?name)", conn)
 da.UpdateCommand = New MySqlCommand("UPDATE mytable SET id=?id, name=?name " & _
 "WHERE id=?oldId", conn)
 da.DeleteCommand = New MySqlCommand("DELETE FROM mytable WHERE id=?id", conn)
 da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
 da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")

 da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
 da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")
 da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
 da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
End Sub
```

C# example:

```
public static void CreateSqlDataAdapter()
{
 MySqlDataAdapter da = new MySqlDataAdapter("SELECT id, name FROM mytable", "Data Source=localhost;database=test");
 MySqlConnection conn = da.SelectCommand.Connection;
 da.MissingSchemaAction = MissingSchemaAction.AddWithKey;

 da.InsertCommand = new MySqlCommand("INSERT INTO mytable (id, name) " +
 "VALUES (?id, ?name)", conn);
 da.UpdateCommand = new MySqlCommand("UPDATE mytable SET id=?id, name=?name " +
 "WHERE id=?oldId", conn);
 da.DeleteCommand = new MySqlCommand("DELETE FROM mytable WHERE id=?id", conn);
 da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
 da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");

 da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
 da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");
 da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original;
 da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original;
}
```

### 29.2.3.4.5. DeleteCommand

Gets or sets a SQL statement or stored procedure used to delete records from the data set.

**Value:** A `MySqlCommand` used during `System.Data.Common.DataAdapter.Update` to delete records in the database that correspond to deleted rows in the `DataSet`.

During `System.Data.Common.DataAdapter.Update`, if this property is not set and primary key information is present in the `DataSet`, the `DeleteCommand` can be generated automatically if you set the `SelectCommand` property and use the `MySqlCommandBuilder`. Then, any additional commands that you do not set are generated by the `MySqlCommandBuilder`. This generation logic requires key column information to be present in the `DataSet`.

When `DeleteCommand` is assigned to a previously created `MySqlCommand`, the `MySqlCommand` is not cloned. The `DeleteCommand` maintains a reference to the previously created `MySqlCommand` object.

#### Examples

The following example creates a `MySqlDataAdapter` and sets the `SelectCommand` and `DeleteCommand` properties. It assumes you have already created a `MySqlConnection` object.

Visual Basic example:

```
Public Shared Function CreateCustomerAdapter(conn As MySqlConnection) As MySqlDataAdapter
 Dim da As MySqlDataAdapter = New MySqlDataAdapter()
 Dim cmd As MySqlCommand
 Dim parm As MySqlParameter
 ' Create the SelectCommand.
 cmd = New MySqlCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn)
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15)
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15)
 da.SelectCommand = cmd
 ' Create the DeleteCommand.
 cmd = New MySqlCommand("DELETE FROM mytable WHERE id=?id", conn)
 parm = cmd.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
 parm.SourceVersion = DataRowVersion.Original
 da.DeleteCommand = cmd
 Return da
End Function
```

C# example:

```
public static MySqlDataAdapter CreateCustomerAdapter(MySqlConnection conn)
{
 MySqlDataAdapter da = new MySqlDataAdapter();
 MySqlCommand cmd;
 MySqlParameter parm;
 // Create the SelectCommand.
 cmd = new MySqlCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn);
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15);
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15);
 da.SelectCommand = cmd;
 // Create the DeleteCommand.
 cmd = new MySqlCommand("DELETE FROM mytable WHERE id=?id", conn);
 parm = cmd.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
 parm.SourceVersion = DataRowVersion.Original;
 da.DeleteCommand = cmd;
 return da;
}
```

### 29.2.3.4.6. InsertCommand

Gets or sets a SQL statement or stored procedure used to insert records into the data set.

**Value:** A [MySqlCommand](#) used during [System.Data.Common.DataAdapter.Update](#) to insert records into the database that correspond to new rows in the [DataSet](#).

During [System.Data.Common.DataAdapter.Update](#), if this property is not set and primary key information is present in the [DataSet](#), the [InsertCommand](#) can be generated automatically if you set the [SelectCommand](#) property and use the [MySqlCommandBuilder](#). Then, any additional commands that you do not set are generated by the [MySqlCommandBuilder](#). This generation logic requires key column information to be present in the [DataSet](#).

When [InsertCommand](#) is assigned to a previously created [MySqlCommand](#), the [MySqlCommand](#) is not cloned. The [InsertCommand](#) maintains a reference to the previously created [MySqlCommand](#) object.

#### Note

If execution of this command returns rows, these rows may be added to the [DataSet](#) depending on how you set the [MySqlCommand.UpdatedRowSource](#) property of the [MySqlCommand](#) object.

#### Examples

The following example creates a [MySqlDataAdapter](#) and sets the [SelectCommand](#) and [InsertCommand](#) properties. It assumes you have already created a [MySqlConnection](#) object.

Visual Basic example:

```
Public Shared Function CreateCustomerAdapter(conn As MySqlConnection) As MySqlDataAdapter
 Dim da As MySqlDataAdapter = New MySqlDataAdapter()
 Dim cmd As MySqlCommand
 Dim parm As MySqlParameter
 ' Create the SelectCommand.
 cmd = New MySqlCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn)
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15)
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15)
 da.SelectCommand = cmd
 ' Create the InsertCommand.
 cmd = New MySqlCommand("INSERT INTO mytable (id,name) VALUES (?id, ?name)", conn)
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15, "id")
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15, "name")
 da.InsertCommand = cmd

 Return da
End Function
```

C# example:

```
public static MySqlDataAdapter CreateCustomerAdapter(MySqlConnection conn)
{
 MySqlDataAdapter da = new MySqlDataAdapter();
 MySqlCommand cmd;
 MySqlParameter parm;
 // Create the SelectCommand.
 cmd = new MySqlCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn);
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15);
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15);
 da.SelectCommand = cmd;
 // Create the InsertCommand.
 cmd = new MySqlCommand("INSERT INTO mytable (id,name) VALUES (?id,?name)", conn);
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15, "id");
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15, "name");
}
```

```

da.InsertCommand = cmd;
return da;
}

```

### 29.2.3.4.7. UpdateCommand

Gets or sets a SQL statement or stored procedure used to updated records in the data source.

**Value:** A [MySqlCommand](#) used during [System.Data.Common.DataAdapter.Update](#) to update records in the database with data from the [DataSet](#).

During [System.Data.Common.DataAdapter.Update](#), if this property is not set and primary key information is present in the [DataSet](#), the [UpdateCommand](#) can be generated automatically if you set the [SelectCommand](#) property and use the [MySqlCommandBuilder](#). Then, any additional commands that you do not set are generated by the [MySqlCommandBuilder](#). This generation logic requires key column information to be present in the [DataSet](#).

When [UpdateCommand](#) is assigned to a previously created [MySqlCommand](#), the [MySqlCommand](#) is not cloned. The [UpdateCommand](#) maintains a reference to the previously created [MySqlCommand](#) object.

#### Note

If execution of this command returns rows, these rows may be merged with the [DataSet](#) depending on how you set the [MySqlCommand.UpdatedRowSource](#) property of the [MySqlCommand](#) object.

#### Examples

The following example creates a [MySqlDataAdapter](#) and sets the [SelectCommand](#) and [UpdateCommand](#) properties. It assumes you have already created a [MySqlConnection](#) object.

Visual Basic example:

```

Public Shared Function CreateCustomerAdapter(conn As MySqlConnection) As MySqlDataAdapter

 Dim da As MySqlDataAdapter = New MySqlDataAdapter()
 Dim cmd As MySqlCommand
 Dim parm As MySqlParameter
 ' Create the SelectCommand.
 cmd = New MySqlCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn)
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15)
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15)
 da.SelectCommand = cmd
 ' Create the UpdateCommand.
 cmd = New MySqlCommand("UPDATE mytable SET id=?id, name=?name WHERE id=?oldId", conn)
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15, "id")
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15, "name")

 parm = cmd.Parameters.Add("?oldId", MySqlDbType.VarChar, 15, "id")
 parm.SourceVersion = DataRowVersion.Original

 da.UpdateCommand = cmd

 Return da
End Function

```

C# example:

```

public static MySqlDataAdapter CreateCustomerAdapter(MySqlConnection conn)
{
 MySqlDataAdapter da = new MySqlDataAdapter();
 MySqlCommand cmd;
 MySqlParameter parm;
 // Create the SelectCommand.
 cmd = new MySqlCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn);
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15);
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15);
 da.SelectCommand = cmd;
 // Create the UpdateCommand.
 cmd = new MySqlCommand("UPDATE mytable SET id=?id, name=?name WHERE id=?oldId", conn);
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15, "id");
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15, "name");

 parm = cmd.Parameters.Add("?oldId", MySqlDbType.VarChar, 15, "id");
 parm.SourceVersion = DataRowVersion.Original;

 da.UpdateCommand = cmd;
 return da;
}

```

### 29.2.3.4.8. SelectCommand

Gets or sets a SQL statement or stored procedure used to select records in the data source.

**Value:** A `MySqlCommand` used during `System.Data.Common.DbDataAdapter.Fill` to select records from the database for placement in the `DataSet`.

When `SelectCommand` is assigned to a previously created `MySqlCommand`, the `MySqlCommand` is not cloned. The `SelectCommand` maintains a reference to the previously created `MySqlCommand` object.

If the `SelectCommand` does not return any rows, no tables are added to the `DataSet`, and no exception is raised.

### Examples

The following example creates a `MySqlDataAdapter` and sets the `SelectCommand` and `InsertCommand` properties. It assumes you have already created a `MySqlConnection` object.

Visual Basic example:

```
Public Shared Function CreateCustomerAdapter(conn As MySqlConnection) As MySqlDataAdapter
 Dim da As MySqlDataAdapter = New MySqlDataAdapter()
 Dim cmd As MySqlCommand
 Dim parm As MySqlParameter
 ' Create the SelectCommand.
 cmd = New MySqlCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn)
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15)
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15)
 da.SelectCommand = cmd
 ' Create the InsertCommand.
 cmd = New MySqlCommand("INSERT INTO mytable (id,name) VALUES (?id, ?name)", conn)
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15, "id")
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15, "name")
 da.InsertCommand = cmd

 Return da
End Function
```

C# example:

```
public static MySqlDataAdapter CreateCustomerAdapter(MySqlConnection conn)
{
 MySqlDataAdapter da = new MySqlDataAdapter();
 MySqlCommand cmd;
 MySqlParameter parm;
 // Create the SelectCommand.
 cmd = new MySqlCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn);
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15);
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15);
 da.SelectCommand = cmd;
 // Create the InsertCommand.
 cmd = new MySqlCommand("INSERT INTO mytable (id,name) VALUES (?id,?name)", conn);
 cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15, "id");
 cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15, "name");

 da.InsertCommand = cmd;
 return da;
}
```

### 29.2.3.5. Using `MySqlDataReader`

To create a `MySqlDataReader`, you must call the `MySqlCommand.ExecuteReader` method of the `MySqlCommand` object, rather than directly using a constructor.

While the `MySqlDataReader` is in use, the associated `MySqlConnection` is busy serving the `MySqlDataReader`, and no other operations can be performed on the `MySqlConnection` other than closing it. This is the case until the `MySqlDataReader.Close` method of the `MySqlDataReader` is called.

`MySqlDataReader.IsClosed` and `MySqlDataReader.RecordsAffected` are the only properties that you can call after the `MySqlDataReader` is closed. Though the `RecordsAffected` property may be accessed at any time while the `MySqlDataReader` exists, always call `Close` before returning the value of `RecordsAffected` to ensure an accurate return value.

For optimal performance, `MySqlDataReader` avoids creating unnecessary objects or making unnecessary copies of data. As a result, multiple calls to methods such as `MySqlDataReader.GetValue` return a reference to the same object. Use caution if you are modifying the underlying value of the objects returned by methods such as `GetValue`.

### Examples

The following example creates a `MySqlConnection`, a `MySqlCommand`, and a `MySqlDataReader`. The example reads through the data, writing it out to the console. Finally, the example closes the `MySqlDataReader`, then the `MySqlConnection`.

tion.

Visual Basic example:

```
Public Sub ReadMyData(myConnString As String)
 Dim mySelectQuery As String = "SELECT OrderID, CustomerID FROM Orders"
 Dim myConnection As New MySqlConnection(myConnString)
 Dim myCommand As New MySqlCommand(mySelectQuery, myConnection)
 myConnection.Open()
 Dim myReader As MySqlDataReader
 myReader = myCommand.ExecuteReader()
 ' Always call Read before accessing data.
 While myReader.Read()
 Console.WriteLine(myReader.GetInt32(0) & ", " & myReader.GetString(1))
 End While
 ' always call Close when done reading.
 myReader.Close()
 ' Close the connection when done with it.
 myConnection.Close()
End Sub 'ReadMyData
```

C# example:

```
public void ReadMyData(string myConnString) {
 string mySelectQuery = "SELECT OrderID, CustomerID FROM Orders";
 MySqlConnection myConnection = new MySqlConnection(myConnString);
 MySqlCommand myCommand = new MySqlCommand(mySelectQuery, myConnection);
 myConnection.Open();
 MySqlDataReader myReader;
 myReader = myCommand.ExecuteReader();
 // Always call Read before accessing data.
 while (myReader.Read()) {
 Console.WriteLine(myReader.GetInt32(0) + ", " + myReader.GetString(1));
 }
 // always call Close when done reading.
 myReader.Close();
 // Close the connection when done with it.
 myConnection.Close();
}
```

### 29.2.3.5.1. GetBytes

[getBytes](#) returns the number of available bytes in the field. In most cases this is the exact length of the field. However, the number returned may be less than the true length of the field if [getBytes](#) has already been used to obtain bytes from the field. This may be the case, for example, if the [MySqlDataReader](#) is reading a large data structure into a buffer. For more information, see the [SequentialAccess](#) setting for [MySqlCommand.CommandBehavior](#).

If you pass a buffer that is a null reference ([Nothing](#) in Visual Basic), [getBytes](#) returns the length of the field in bytes.

No conversions are performed; therefore the data retrieved must already be a byte array.

### 29.2.3.5.2. GetTimeSpan

Gets the value of the specified column as a [TimeSpan](#) object.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

### 29.2.3.5.3. GetDateTime

Gets the value of the specified column as a [System.DateTime](#) object.

#### Note

MySQL allows date columns to contain the value '0000-00-00' and datetime columns to contain the value '0000-00-00 00:00:00'. The [DateTime](#) structure cannot contain or represent these values. To read a datetime value from a column that might contain zero values, use [GetMySqlDateTime](#). The behavior of reading a zero datetime column using this method is defined by the [ZeroDateTimeBehavior](#) connection string option. For more information on this option, please refer to [MySqlConnection.ConnectionString](#).

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

#### 29.2.3.5.4. GetMySqlDateTime

Gets the value of the specified column as a `MySql.Data.Types.MySqlDateTime` object.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

#### 29.2.3.5.5. GetString

Gets the value of the specified column as a `String` object.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

#### 29.2.3.5.6. GetDecimal

Gets the value of the specified column as a `Decimal` object.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

#### 29.2.3.5.7. GetDouble

Gets the value of the specified column as a double-precision floating point number.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

#### 29.2.3.5.8. GetFloat

Gets the value of the specified column as a single-precision floating point number.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

#### 29.2.3.5.9. GetGuid

Gets the value of the specified column as a globally-unique identifier (GUID).

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

#### 29.2.3.5.10. GetInt16

Gets the value of the specified column as a 16-bit signed integer.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

#### 29.2.3.5.11. GetInt32

Gets the value of the specified column as a 32-bit signed integer.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

#### 29.2.3.5.12. GetInt64

Gets the value of the specified column as a 64-bit signed integer.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

### 29.2.3.5.13. GetUInt16

Gets the value of the specified column as a 16-bit unsigned integer.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

### 29.2.3.5.14. GetUInt32

Gets the value of the specified column as a 32-bit unsigned integer.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

### 29.2.3.5.15. GetUInt64

Gets the value of the specified column as a 64-bit unsigned integer.

**Parameters:** The zero-based column ordinal.

**Returns:** The value of the specified column.

## 29.2.3.6. Using [MySqlException](#)

This class is created whenever the MySQL Data Provider encounters an error generated from the server.

Any open connections are not automatically closed when an exception is thrown. If the client application determines that the exception is fatal, it should close any open [MySqlDataReader](#) objects or [MySqlConnection](#) objects.

### Examples

The following example generates a [MySqlException](#) due to a missing server, and then displays the exception.

Visual Basic example:

```
Public Sub ShowException()
 Dim mySelectQuery As String = "SELECT column1 FROM table1"
 Dim myConnection As New MySqlConnection ("Data Source=localhost;Database=Sample;")
 Dim myCommand As New MySqlCommand(mySelectQuery, myConnection)
 Try
 myCommand.Connection.Open()
 Catch e As MySqlException
 MessageBox.Show(e.Message)
 End Try
End Sub
```

C# example:

```
public void ShowException()
{
 string mySelectQuery = "SELECT column1 FROM table1";
 MySqlConnection myConnection =
 new MySqlConnection("Data Source=localhost;Database=Sample;");
 MySqlCommand myCommand = new MySqlCommand(mySelectQuery, myConnection);
 try
 {
 myCommand.Connection.Open();
 }
 catch (MySqlException e)
 {
 MessageBox.Show(e.Message);
 }
}
```

## 29.2.3.7. Using [MySqlParameter](#)

Parameter names are not case sensitive.

### Examples

The following example creates multiple instances of [MySQLParameter](#) through the [MySQLParameterCollection](#) collection within the [MySQLDataAdapter](#). These parameters are used to select data from the data source and place the data in the [DataSet](#). This example assumes that a [DataSet](#) and a [MySQLDataAdapter](#) have already been created with the appropriate schema, commands, and connection.

Visual Basic example:

```
Public Sub AddSqlParameters()
 ' ...
 ' create myDataSet and myDataAdapter
 ' ...
 myDataAdapter.SelectCommand.Parameters.Add("@CategoryName", MySQLDbType.VarChar, 80).Value = "toasters"
 myDataAdapter.SelectCommand.Parameters.Add("@SerialNum", MySQLDbType.Long).Value = 239
 myDataAdapter.Fill(myDataSet)
End Sub 'AddSqlParameters
```

C# example:

```
public void AddSqlParameters()
{
 // ...
 // create myDataSet and myDataAdapter
 // ...
 myDataAdapter.SelectCommand.Parameters.Add("@CategoryName", MySQLDbType.VarChar, 80).Value = "toasters";
 myDataAdapter.SelectCommand.Parameters.Add("@SerialNum", MySQLDbType.Long).Value = 239;
 myDataAdapter.Fill(myDataSet);
}
```

### 29.2.3.8. Using [MySQLParameterCollection](#)

The number of the parameters in the collection must be equal to the number of parameter placeholders within the command text, or an exception will be generated.

#### Examples

The following example creates multiple instances of [MySQLParameter](#) through the [MySQLParameterCollection](#) collection within the [MySQLDataAdapter](#). These parameters are used to select data within the data source and place the data in the [DataSet](#). This code assumes that a [DataSet](#) and a [MySQLDataAdapter](#) have already been created with the appropriate schema, commands, and connection.

Visual Basic example:

```
Public Sub AddParameters()
 ' ...
 ' create myDataSet and myDataAdapter
 ' ...
 myDataAdapter.SelectCommand.Parameters.Add("@CategoryName", MySQLDbType.VarChar, 80).Value = "toasters"
 myDataAdapter.SelectCommand.Parameters.Add("@SerialNum", MySQLDbType.Long).Value = 239
 myDataAdapter.Fill(myDataSet)
End Sub 'AddSqlParameters
```

C# example:

```
public void AddSqlParameters()
{
 // ...
 // create myDataSet and myDataAdapter
 // ...
 myDataAdapter.SelectCommand.Parameters.Add("@CategoryName", MySQLDbType.VarChar, 80).Value = "toasters";
 myDataAdapter.SelectCommand.Parameters.Add("@SerialNum", MySQLDbType.Long).Value = 239;
 myDataAdapter.Fill(myDataSet);
}
```

### 29.2.3.9. Using [MySQLTransaction](#)

Represents a SQL transaction to be made in a MySQL database. This class cannot be inherited.

The application creates a [MySQLTransaction](#) object by calling [MySQLConnection.BeginTransaction](#) on the [MySQLConnection](#) object. All subsequent operations associated with the transaction (for example, committing or aborting the transaction), are performed on the [MySQLTransaction](#) object.

#### ■ Note

Once you have started a transaction on a connection all subsequent commands on that connection are applied within the scope of the transaction. You cannot execute an SQL statement on the same connection outside of the transaction scope. If you need to do this while executing statements that are part of a transaction, open a second a connection to be used for execution the non-transaction statements.

### Examples

The following example creates a `MySqlConnection` and a `MySqlTransaction`. It also demonstrates how to use the `MySqlConnection.BeginTransaction`, `MySqlTransaction.Commit`, and `MySqlTransaction.Rollback` methods.

Visual Basic example:

```
Public Sub RunTransaction(myConnString As String)
 Dim myConnection As New MySqlConnection(myConnString)
 myConnection.Open()

 Dim myCommand As MySqlCommand = myConnection.CreateCommand()
 Dim myTrans As MySqlTransaction

 ' Start a local transaction
 myTrans = myConnection.BeginTransaction()
 ' Must assign both transaction object and connection
 ' to Command object for a pending local transaction
 myCommand.Connection = myConnection
 myCommand.Transaction = myTrans

 Try
 myCommand.CommandText = "Insert into Region (RegionID, RegionDescription) VALUES (100, 'Description')"
 myCommand.ExecuteNonQuery()
 myCommand.CommandText = "Insert into Region (RegionID, RegionDescription) VALUES (101, 'Description')"
 myCommand.ExecuteNonQuery()
 myTrans.Commit()
 Console.WriteLine("Both records are written to database.")
 Catch e As Exception
 Try
 myTrans.Rollback()
 Catch ex As MySqlException
 If Not myTrans.Connection Is Nothing Then
 Console.WriteLine("An exception of type " & ex.GetType().ToString() & _
 " was encountered while attempting to roll back the transaction.")
 End If
 End Try

 Console.WriteLine("An exception of type " & e.GetType().ToString() & _
 " was encountered while inserting the data.")
 Console.WriteLine("Neither record was written to database.")
 Finally
 myConnection.Close()
 End Try
End Sub 'RunTransaction
```

C# example:

```
public void RunTransaction(string myConnString)
{
 MySqlConnection myConnection = new MySqlConnection(myConnString);
 myConnection.Open();
 MySqlCommand myCommand = myConnection.CreateCommand();
 MySqlTransaction myTrans;
 // Start a local transaction
 myTrans = myConnection.BeginTransaction();
 // Must assign both transaction object and connection
 // to Command object for a pending local transaction
 myCommand.Connection = myConnection;
 myCommand.Transaction = myTrans;
 try
 {
 myCommand.CommandText = "Insert into Region (RegionID, RegionDescription) VALUES (100, 'Description')";
 myCommand.ExecuteNonQuery();
 myCommand.CommandText = "Insert into Region (RegionID, RegionDescription) VALUES (101, 'Description')";
 myCommand.ExecuteNonQuery();
 myTrans.Commit();
 Console.WriteLine("Both records are written to database.");
 }
 catch (Exception e)
 {
 try
 {
 myTrans.Rollback();
 }
 catch (MySqlException ex)
 {
 if (myTrans.Connection != null)
 {
 Console.WriteLine("An exception of type " + ex.GetType() +
 " was encountered while attempting to roll back the transaction.");
 }
 }
 }
}
```

```

 Console.WriteLine("An exception of type " + e.GetType() +
 " was encountered while inserting the data.");
 Console.WriteLine("Neither record was written to database.");
 }
 finally
 {
 myConnection.Close();
 }
}

```

### 29.2.3.9.1. Rollback

Rolls back a transaction from a pending state.

The Rollback method is equivalent to the MySQL statement ROLLBACK. The transaction can only be rolled back from a pending state (after BeginTransaction has been called, but before Commit is called).

#### Examples

The following example creates [MySQLConnection](#) and a [MySQLTransaction](#). It also demonstrates how to use the [MySQLConnection.BeginTransaction](#), [Commit](#), and [Rollback](#) methods.

Visual Basic example:

```

Public Sub RunSqlTransaction(myConnString As String)
 Dim myConnection As New MySqlConnection(myConnString)
 myConnection.Open()

 Dim myCommand As MySqlCommand = myConnection.CreateCommand()
 Dim myTrans As MySQLTransaction

 ' Start a local transaction
 myTrans = myConnection.BeginTransaction()

 ' Must assign both transaction object and connection
 ' to Command object for a pending local transaction
 myCommand.Connection = myConnection
 myCommand.Transaction = myTrans

 Try
 myCommand.CommandText = "Insert into mytable (id, desc) VALUES (100, 'Description')"
 myCommand.ExecuteNonQuery()
 myCommand.CommandText = "Insert into mytable (id, desc) VALUES (101, 'Description')"
 myCommand.ExecuteNonQuery()
 myTrans.Commit()
 Console.WriteLine("Success.")
 Catch e As Exception
 Try
 myTrans.Rollback()
 Catch ex As MySQLException
 If Not myTrans.Connection Is Nothing Then
 Console.WriteLine("An exception of type " & ex.GetType().ToString() & _
 " was encountered while attempting to roll back the transaction.")
 End If
 End Try

 Console.WriteLine("An exception of type " & e.GetType().ToString() & _
 "was encountered while inserting the data.")
 Console.WriteLine("Neither record was written to database.")
 Finally
 myConnection.Close()
 End Try
End Sub

```

C# example:

```

public void RunSqlTransaction(string myConnString)
{
 MySqlConnection myConnection = new MySqlConnection(myConnString);
 myConnection.Open();
 MySqlCommand myCommand = myConnection.CreateCommand();
 MySQLTransaction myTrans;
 // Start a local transaction
 myTrans = myConnection.BeginTransaction();
 // Must assign both transaction object and connection
 // to Command object for a pending local transaction
 myCommand.Connection = myConnection;
 myCommand.Transaction = myTrans;
 try
 {
 myCommand.CommandText = "Insert into mytable (id, desc) VALUES (100, 'Description')";
 myCommand.ExecuteNonQuery();
 myCommand.CommandText = "Insert into mytable (id, desc) VALUES (101, 'Description')";
 myCommand.ExecuteNonQuery();
 myTrans.Commit();
 Console.WriteLine("Both records are written to database.");
 }
}

```

```

}
catch(Exception e)
{
 try
 {
 myTrans.Rollback();
 }
 catch (MySqlException ex)
 {
 if (myTrans.Connection != null)
 {
 Console.WriteLine("An exception of type " + ex.GetType() +
 " was encountered while attempting to roll back the transaction.");
 }
 }

 Console.WriteLine("An exception of type " + e.GetType() +
 " was encountered while inserting the data.");
 Console.WriteLine("Neither record was written to database.");
}
finally
{
 myConnection.Close();
}
}

```

### 29.2.3.9.2. Commit

Commits the database transaction.

The `Commit` method is equivalent to the MySQL SQL statement `COMMIT`.

#### Examples

The following example creates `MySqlConnection` and a `MySqlTransaction`. It also demonstrates how to use the `MySqlConnection.BeginTransaction`, `Commit`, and `Rollback` methods.

Visual Basic example:

```

Public Sub RunSqlTransaction(myConnString As String)
 Dim myConnection As New MySqlConnection(myConnString)
 myConnection.Open()

 Dim myCommand As MySqlCommand = myConnection.CreateCommand()
 Dim myTrans As MySqlTransaction

 ' Start a local transaction
 myTrans = myConnection.BeginTransaction()

 ' Must assign both transaction object and connection
 ' to Command object for a pending local transaction
 myCommand.Connection = myConnection
 myCommand.Transaction = myTrans

 Try
 myCommand.CommandText = "Insert into mytable (id, desc) VALUES (100, 'Description')"
 myCommand.ExecuteNonQuery()
 myCommand.CommandText = "Insert into mytable (id, desc) VALUES (101, 'Description')"
 myCommand.ExecuteNonQuery()
 myTrans.Commit()
 Console.WriteLine("Success.")
 Catch e As Exception
 Try
 myTrans.Rollback()
 Catch ex As MySqlException
 If Not myTrans.Connection Is Nothing Then
 Console.WriteLine("An exception of type " & ex.GetType().ToString() & _
 " was encountered while attempting to roll back the transaction.")
 End If
 End Try

 Console.WriteLine("An exception of type " & e.GetType().ToString() & _
 " was encountered while inserting the data.")
 Console.WriteLine("Neither record was written to database.")
 Finally
 myConnection.Close()
 End Try
End Sub

```

C# example:

```

public void RunSqlTransaction(string myConnString)
{
 MySqlConnection myConnection = new MySqlConnection(myConnString);
 myConnection.Open();
 MySqlCommand myCommand = myConnection.CreateCommand();
 MySqlTransaction myTrans;
 // Start a local transaction
 myTrans = myConnection.BeginTransaction();

```

```

// Must assign both transaction object and connection
// to Command object for a pending local transaction
myCommand.Connection = myConnection;
myCommand.Transaction = myTrans;
try
{
 myCommand.CommandText = "Insert into mytable (id, desc) VALUES (100, 'Description')";
 myCommand.ExecuteNonQuery();
 myCommand.CommandText = "Insert into mytable (id, desc) VALUES (101, 'Description')";
 myCommand.ExecuteNonQuery();
 myTrans.Commit();
 Console.WriteLine("Both records are written to database.");
}
catch(Exception e)
{
 try
 {
 myTrans.Rollback();
 }
 catch (MySqlException ex)
 {
 if (myTrans.Connection != null)
 {
 Console.WriteLine("An exception of type " + ex.GetType() +
 " was encountered while attempting to roll back the transaction.");
 }
 }

 Console.WriteLine("An exception of type " + e.GetType() +
 " was encountered while inserting the data.");
 Console.WriteLine("Neither record was written to database.");
}
finally
{
 myConnection.Close();
}
}

```

## 29.2.4. Connector/NET Reference

This section of the manual contains a complete reference to the Connector/NET ADO.NET component, automatically generated from the embedded documentation.

### 29.2.4.1. `MySql.Data.MySqlClient`

#### Classes

| Class                                     | Description                                                                                                                                                                    |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">MySqlCommand</a>              |                                                                                                                                                                                |
| <a href="#">MySqlCommandBuilder</a>       |                                                                                                                                                                                |
| <a href="#">MySqlConnection</a>           |                                                                                                                                                                                |
| <a href="#">MySqlDataAdapter</a>          |                                                                                                                                                                                |
| <a href="#">MySqlDataReader</a>           | Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.                                                               |
| <a href="#">MySqlError</a>                | Collection of error codes that can be returned by the server                                                                                                                   |
| <a href="#">MySqlException</a>            | The exception that is thrown when MySQL returns an error. This class cannot be inherited.                                                                                      |
| <a href="#">MySqlHelper</a>               | Helper class that makes it easier to work with the provider.                                                                                                                   |
| <a href="#">MySqlInfoMessageEventArgs</a> | Provides data for the InfoMessage event. This class cannot be inherited.                                                                                                       |
| <a href="#">MySqlParameter</a>            | Represents a parameter to a <a href="#">MySqlCommand</a> , and optionally, its mapping to DataSet columns. This class cannot be inherited.                                     |
| <a href="#">MySqlParameterCollection</a>  | Represents a collection of parameters relevant to a <a href="#">MySqlCommand</a> as well as their respective mappings to columns in a DataSet. This class cannot be inherited. |
| <a href="#">MySqlRowUpdatedEventArgs</a>  | Provides data for the RowUpdated event. This class cannot be inherited.                                                                                                        |
| <a href="#">MySqlRowUpdatingEventArgs</a> | Provides data for the RowUpdating event. This class cannot be inherited.                                                                                                       |
| <a href="#">MySqlTransaction</a>          |                                                                                                                                                                                |

**Delegates**

| Delegate                                     | Description                                                                                                         |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <a href="#">MySqlInfoMessageEventHandler</a> | Represents the method that will handle the <a href="#">InfoMessage</a> event of a <a href="#">MySqlConnection</a> . |
| <a href="#">MySqlRowUpdatedEventHandler</a>  | Represents the method that will handle the RowUpdatedevent of a <a href="#">MySqlDataAdapter</a> .                  |
| <a href="#">MySqlRowUpdatingEventHandler</a> | Represents the method that will handle the RowUpdatingevent of a <a href="#">MySqlDataAdapter</a> .                 |

**Enumerations**

| Enumeration                    | Description                                                                                            |
|--------------------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">MySqlDbType</a>    | Specifies MySQL specific data type of a field, property, for use in a <a href="#">MySqlParameter</a> . |
| <a href="#">MySqlErrorCode</a> |                                                                                                        |

**29.2.4.1.1. [MySql.Data.MySqlCommandHierarchy](#)****See Also**

[MySql.Data.MySqlCommand](#) Namespace

**29.2.4.1.2. [MySqlCommand](#) Class**

For a list of all members of this type, see [MySqlCommand Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlCommand_
 Inherits Component_
 Implements IDbCommand, ICloneable
```

**Syntax: C#**

```
public sealed class MySqlCommand : Component, IDbCommand, ICloneable
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySql.Data.MySqlCommand](#)

Assembly: MySql.Data (in MySql.Data.dll)

| Site(inherited from Component)      | Gets or sets the ISiteof the Component.         |
| <a href="#">Transaction</a>         |                                                 |
| <a href="#">UpdatedRowSource</a>    |                                                 |

**Public Instance Methods**

|                                                              |                                                                                                                                              |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Cancel</a>                                       | Attempts to cancel the execution of a MySqlCommand. This operation is not supported.                                                         |
| CreateObjRef(inherited from MarshalByRefObject)              | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.          |
| <a href="#">CreateParameter</a>                              | Creates a new instance of a <a href="#">MySqlParameter</a> object.                                                                           |
| Dispose(inherited from Component)                            | Releases all resources used by the Component.                                                                                                |
| Equals(inherited from Object)                                | Determines whether the specified Objectis equal to the current Object.                                                                       |
| <a href="#">ExecuteNonQuery</a>                              |                                                                                                                                              |
| <a href="#">ExecuteReader</a>                                | Overloaded.                                                                                                                                  |
| <a href="#">ExecuteScalar</a>                                |                                                                                                                                              |
| GetHashCode(inherited from Object)                           | Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table. |
| GetLifetimeService(inherited from MarshalByRefObject)        | Retrieves the current lifetime service object that controls the lifetime policy for this instance.                                           |
| GetType(inherited from Object)                               | Gets the Typeof the current instance.                                                                                                        |
| InitializeLifetimeService(inherited from MarshalByRefObject) | Obtains a lifetime service object to control the lifetime policy for this instance.                                                          |
| <a href="#">Prepare</a>                                      |                                                                                                                                              |
| ToString(inherited from Component)                           | Returns a Stringcontaining the name of the Component, if any. This method should not be overridden.                                          |

**Public Instance Events**

|                                    |                                                                        |
|------------------------------------|------------------------------------------------------------------------|
| Disposed(inherited from Component) | Adds an event handler to listen to the Disposedevent on the component. |
|------------------------------------|------------------------------------------------------------------------|

|                                 |                                                                      |
|---------------------------------|----------------------------------------------------------------------|
| <a href="#">MySqlConnection</a> | Overloaded. Initializes a new instance of the MySqlConnection class. |
|---------------------------------|----------------------------------------------------------------------|

**Public Instance Properties**

|                                     |                                                                                         |
|-------------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">ConnectionString</a>    |                                                                                         |
| <a href="#">ConnectionTimeout</a>   |                                                                                         |
| Container(inherited from Component) | Gets the IContainerthat contains the Component.                                         |
| <a href="#">Database</a>            |                                                                                         |
| <a href="#">DataSource</a>          | Gets the name of the MySQL server to which to connect.                                  |
| <a href="#">ServerThread</a>        | Returns the id of the server thread this connection is executing on                     |
| <a href="#">ServerVersion</a>       |                                                                                         |
| Site(inherited from Component)      | Gets or sets the ISiteof the Component.                                                 |
| <a href="#">State</a>               |                                                                                         |
| <a href="#">UseCompression</a>      | Indicates if this connection should use compression when communicating with the server. |

**Public Instance Methods**

|                                                       |                                                                                                                                              |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">BeginTransaction</a>                      | Overloaded.                                                                                                                                  |
| <a href="#">ChangeDatabase</a>                        |                                                                                                                                              |
| <a href="#">Close</a>                                 |                                                                                                                                              |
| <a href="#">CreateCommand</a>                         |                                                                                                                                              |
| CreateObjRef(inherited from MarshalByRefObject)       | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.          |
| Dispose(inherited from Component)                     | Releases all resources used by the Component.                                                                                                |
| Equals(inherited from Object)                         | Determines whether the specified Objectis equal to the current Object.                                                                       |
| GetHashCode(inherited from Object)                    | Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table. |
| GetLifetimeService(inherited from MarshalByRefObject) | Retrieves the current lifetime service object that controls the lifetime policy for this instance.                                           |

|                                                              |                                                                                                     |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| GetType(inherited from Object)                               | Gets the Typeof the current instance.                                                               |
| InitializeLifetimeService(inherited from MarshalByRefObject) | Obtains a lifetime service object to control the lifetime policy for this instance.                 |
| <a href="#">Open</a>                                         |                                                                                                     |
| <a href="#">Ping</a>                                         | Ping                                                                                                |
| ToString(inherited from Component)                           | Returns a Stringcontaining the name of the Component, if any. This method should not be overridden. |

**Public Instance Events**

|                                    |                                                                        |
|------------------------------------|------------------------------------------------------------------------|
| Disposed(inherited from Component) | Adds an event handler to listen to the Disposedevent on the component. |
| <a href="#">InfoMessage</a>        |                                                                        |
| <a href="#">StateChange</a>        |                                                                        |

| ToString(inherited from Object)    | Returns a String that represents the current Object.                                                                                          |

**See Also**

[MySQLTransaction Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.1.3.1.1.10.1.1.1.1. Connection Property

Gets the [MySQLConnection](#) object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid.

**Syntax: Visual Basic**

```
Public ReadOnly Property Connection As MySqlConnection
```

**Syntax: C#**

```
public MySqlConnection Connection {get;}
```

**Property Value**

The [MySQLConnection](#) object associated with this transaction.

**Remarks**

A single application may have multiple database connections, each with zero or more transactions. This property enables you to determine the connection object associated with a particular transaction created by [BeginTransaction](#) .

**See Also**

[MySQLTransaction Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.1.3.1.1.10.1.1.1.2. IsolationLevel Property

Specifies the IsolationLevel for this transaction.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property IsolationLevel As IsolationLevel _
_ Implements IDbTransaction.IsolationLevel
```

**Syntax: C#**

```
public System.Data.IsolationLevel IsolationLevel {get;}
```

**Property Value**

The IsolationLevel for this transaction. The default is ReadCommitted.

**Implements**

IDbTransaction.IsolationLevel

**Remarks**

Parallel transactions are not supported. Therefore, the IsolationLevel applies to the entire transaction.

**See Also**

[MySQLTransaction Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.1.3.1.1.10.1.1.1.3. [MySQLTransaction.Commit](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Sub Commit() _
 Implements IDbTransaction.Commit
```

**Syntax: C#**

```
public void Commit();
```

**Implements**

IDbTransaction.Commit

**See Also**

[MySQLTransaction Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.1.3.1.1.10.1.1.1.4. [MySQLTransaction.Rollback](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Sub Rollback() _
 Implements IDbTransaction.Rollback
```

**Syntax: C#**

```
public void Rollback();
```

**Implements**

IDbTransaction.Rollback

**See Also**

[MySQLTransaction Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.1.3.1.1.10.2. [MySQLConnection.BeginTransaction](#) Method**Syntax: Visual Basic**

```
Overloads Public Function BeginTransaction(_
 ByVal iso As IsolationLevel _
) As MySQLTransaction
```

**Syntax: C#**

```
public MySQLTransaction BeginTransaction(
 IsolationLevel iso
);
```

**See Also**

[MySQLConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLConnection.BeginTransaction Overload List](#)

29.2.4.1.2.1.1.3.1.1.11. [MySQLConnection.ChangeDatabase](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Sub ChangeDatabase(_
```

```
ByVal databaseName As String _
) _
- Implements IDbConnection.ChangeDatabase
```

**Syntax: C#**

```
public void ChangeDatabase(
string databaseName
);
```

**Implements**

IDbConnection.ChangeDatabase

**See Also**

[MySQLConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.1.3.1.1.12. [MySQLConnection.Close](#) Method

**Syntax: Visual Basic**

```
NotOverridable Public Sub Close() _
- Implements IDbConnection.Close
```

**Syntax: C#**

```
public void Close();
```

**Implements**

IDbConnection.Close

**See Also**

[MySQLConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.1.3.1.1.13. [MySQLConnection.CreateCommand](#) Method

**Syntax: Visual Basic**

```
Public Function CreateCommand() As MySqlCommand
```

**Syntax: C#**

```
public MySqlCommand CreateCommand();
```

**See Also**

[MySQLConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.1.3.1.1.14. [MySQLConnection.Open](#) Method

**Syntax: Visual Basic**

```
NotOverridable Public Sub Open() _
- Implements IDbConnection.Open
```

**Syntax: C#**

```
public void Open();
```

**Implements**

IDbConnection.Open

**See Also**

[MySQLConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.1.3.1.1.15. [MySQLConnection.Ping](#) Method

Ping

##### Syntax: Visual Basic

```
Public Function Ping() As Boolean
```

##### Syntax: C#

```
public bool Ping();
```

##### Return Value

##### See Also

[MySQLConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.1.3.1.1.16. [MySQLConnection.InfoMessage](#) Event

##### Syntax: Visual Basic

```
Public Event InfoMessage As MySqlInfoMessageEventHandler
```

##### Syntax: C#

```
public event MySqlInfoMessageEventHandler InfoMessage;
```

##### See Also

[MySQLConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.1.3.1.1.16.1. [MySQLInfoMessageEventHandler](#) Delegate

Represents the method that will handle the [InfoMessage](#) event of a [MySQLConnection](#) .

##### Syntax: Visual Basic

```
Public Delegate Sub MySqlInfoMessageEventHandler(_
 ByVal sender As Object, _
 ByVal args As MySqlInfoMessageEventArgs _
)
```

##### Syntax: C#

```
public delegate void MySqlInfoMessageEventHandler(
 object sender,
 MySqlInfoMessageEventArgs args
);
```

##### Requirements

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySQL.Data (in MySQL.Data.dll)

##### See Also

[MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.1.3.1.1.16.1.1. [MySQLInfoMessageEventArgs](#) Class

Provides data for the [InfoMessage](#) event. This class cannot be inherited.

For a list of all members of this type, see [MySQLInfoMessageEventArgs Members](#) .

##### Syntax: Visual Basic

```
Public Class MySqlInfoMessageEventArgs_
```

Inherits EventArgs

**Syntax: C#**

```
public class MySqlInfoMessageEventArgs : EventArgs
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySql.Data.MySqlCommand](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

**Syntax: Visual Basic**

```
NotOverridable Public Property CommandText As String _
 Implements IDbCommand.CommandText
```

**Syntax: C#**

```
public string CommandText {get; set;}
```

**Implements**

IDbCommand.CommandText

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.3. CommandTimeout Property

**Syntax: Visual Basic**

```
NotOverridable Public Property CommandTimeout As Integer _
 Implements IDbCommand.CommandTimeout
```

**Syntax: C#**

```
public int CommandTimeout {get; set;}
```

**Implements**

IDbCommand.CommandTimeout

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.4. CommandType Property

**Syntax: Visual Basic**

```
NotOverridable Public Property CommandType As CommandType _
 Implements IDbCommand.CommandType
```

**Syntax: C#**

```
public System.Data.CommandType CommandType {get; set;}
```

**Implements**

IDbCommand.CommandType

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.5. Connection Property

**Syntax: Visual Basic**

```
Public Property Connection As MySqlConnection
```

**Syntax: C#**

```
public MySqlConnection Connection {get; set;}
```

**See Also**

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.6. IsPrepared Property

**Syntax: Visual Basic**

Public ReadOnly Property IsPrepared As Boolean
```

**Syntax: C#**

```
public bool IsPrepared {get;}
```

**See Also**

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.7. Parameters Property

**Syntax: Visual Basic**

```
Public ReadOnly Property Parameters As MySqlParameterCollection
```

**Syntax: C#**

```
public MySqlParameterCollection Parameters {get;}
```

**See Also**

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.7.1. [MySqlParameterCollection](#) Class

Represents a collection of parameters relevant to a [MySQLCommand](#) as well as their respective mappings to columns in a DataSet. This class cannot be inherited.

For a list of all members of this type, see [MySqlParameterCollection Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlParameterCollection_
 Inherits MarshalByRefObject_
 Implements IDataParameterCollection, IList, ICollection, IEnumerable
```

**Syntax: C#**

```
public sealed class MySqlParameterCollection : MarshalByRefObject, IDataParameterCollection, IList, ICollection, IEnumerable
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySQL.Data (in MySQL.Data.dll)

**See Also**

**Public Instance Constructors**

|                                                      |                                                                                   |
|------------------------------------------------------|-----------------------------------------------------------------------------------|
| <a href="#">MySQLParameterCollection Constructor</a> | Initializes a new instance of the <a href="#">MySQLParameterCollection</a> class. |
|------------------------------------------------------|-----------------------------------------------------------------------------------|

**Public Instance Properties**

|                       |                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Count</a> | Gets the number of <a href="#">MySQLParameter</a> objects in the collection.                                                                                                |
| <a href="#">Item</a>  | Overloaded. Gets the <a href="#">MySQLParameter</a> with a specified attribute. In C#, this property is the indexer for the <a href="#">MySQLParameterCollection</a> class. |

**Public Instance Methods**

|                                                              |                                                                                                                                               |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Add</a>                                          | Overloaded. Adds the specified <a href="#">MySQLParameter</a> object to the <a href="#">MySQLParameterCollection</a> .                        |
| <a href="#">Clear</a>                                        | Removes all items from the collection.                                                                                                        |
| <a href="#">Contains</a>                                     | Overloaded. Gets a value indicating whether a <a href="#">MySQLParameter</a> exists in the collection.                                        |
| <a href="#">CopyTo</a>                                       | Copies <a href="#">MySQLParameter</a> objects from the <a href="#">MySQLParameterCollection</a> to the specified array.                       |
| CreateObjRef(inherited from MarshalByRefObject)              | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.           |
| Equals(inherited from Object)                                | Determines whether the specified Object is equal to the current Object.                                                                       |
| GetHashCode(inherited from Object)                           | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetLifetimeService(inherited from MarshalByRefObject)        | Retrieves the current lifetime service object that controls the lifetime policy for this instance.                                            |
| GetType(inherited from Object)                               | Gets the Type of the current instance.                                                                                                        |
| <a href="#">IndexOf</a>                                      | Overloaded. Gets the location of a <a href="#">MySQLParameter</a> in the collection.                                                          |
| InitializeLifetimeService(inherited from MarshalByRefObject) | Obtains a lifetime service object to control the lifetime policy for this instance.                                                           |
| <a href="#">Insert</a>                                       | Inserts a <a href="#">MySQLParameter</a> into the collection at the specified index.                                                          |
| <a href="#">Remove</a>                                       | Removes the specified <a href="#">MySQLParameter</a> from the collection.                                                                     |
| <a href="#">RemoveAt</a>                                     | Overloaded. Removes the specified <a href="#">MySQLParameter</a> from the collection.                                                         |
| ToString(inherited from Object)                              | Returns a String that represents the current Object.                                                                                          |

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.2.1.7.1.1.1. MySQLParameterCollection Constructor**

Initializes a new instance of the [MySQLParameterCollection](#) class.

**Syntax: Visual Basic**

```
Public Sub New()
```

**Syntax: C#**

```
public MySQLParameterCollection();
```

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.7.1.1.2. Count Property

Gets the number of [MySQLParameter](#) objects in the collection.

##### Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property Count As Integer _
 Implements ICollection.Count
```

##### Syntax: C#

```
public int Count {get;}
```

##### Implements

[ICollection.Count](#)

##### See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.7.1.1.3. Item Property

Gets the [MySQLParameter](#) with a specified attribute. In C#, this property is the indexer for the [MySQLParameterCollection](#) class.

##### Overload List

Gets the [MySQLParameter](#) at the specified index.

- `public MySQLParameter this[int] {get; set;}`

Gets the [MySQLParameter](#) with the specified name.

- `public MySQLParameter this[string] {get; set;}`

##### See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.7.1.1.3.1. MySQLParameter Class

Represents a parameter to a [MySQLCommand](#) , and optionally, its mapping to [DataSetColumns](#). This class cannot be inherited.

For a list of all members of this type, see [MySQLParameter Members](#) .

##### Syntax: Visual Basic

```
NotInheritable Public Class MySQLParameter_
 Inherits MarshalByRefObject_
 Implements IDataParameter, IDbDataParameter, ICloneable
```

##### Syntax: C#

```
public sealed class MySQLParameter : MarshalByRefObject, IDataParameter, IDbDataParameter, ICloneable
```

##### Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

##### Requirements

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

#### Public Instance Constructors

|                                |                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------|
| <a href="#">MySqlParameter</a> | Overloaded. Initializes a new instance of the <a href="#">MySqlParameter</a> class. |
|--------------------------------|-------------------------------------------------------------------------------------|

#### Public Instance Properties

|                               |                                                                                                                                                                                                                          |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DbType</a>        | Gets or sets the <a href="#">DbType</a> of the parameter.                                                                                                                                                                |
| <a href="#">Direction</a>     | Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice. |
| <a href="#">IsNullable</a>    | Gets or sets a value indicating whether the parameter accepts null values.                                                                                                                                               |
| <a href="#">IsUnsigned</a>    |                                                                                                                                                                                                                          |
| <a href="#">MySqlDbType</a>   | Gets or sets the <a href="#">MySqlDbType</a> of the parameter.                                                                                                                                                           |
| <a href="#">ParameterName</a> | Gets or sets the name of the <a href="#">MySqlParameter</a> .                                                                                                                                                            |
| <a href="#">Precision</a>     | Gets or sets the maximum number of digits used to represent the <a href="#">Value</a> property.                                                                                                                          |
| <a href="#">Scale</a>         | Gets or sets the number of decimal places to which <a href="#">Value</a> is resolved.                                                                                                                                    |
| <a href="#">Size</a>          | Gets or sets the maximum size, in bytes, of the data within the column.                                                                                                                                                  |
| <a href="#">SourceColumn</a>  | Gets or sets the name of the source column that is mapped to the <a href="#">DataSet</a> and used for loading or returning the <a href="#">Value</a> .                                                                   |
| <a href="#">SourceVersion</a> | Gets or sets the <a href="#">DataRowVersion</a> to use when loading <a href="#">Value</a> .                                                                                                                              |
| <a href="#">Value</a>         | Gets or sets the value of the parameter.                                                                                                                                                                                 |

#### Public Instance Methods

|                                                                                                |                                                                                                                                                               |
|------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CreateObjRef</a> (inherited from <a href="#">MarshalByRefObject</a> )              | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.                           |
| <a href="#">Equals</a> (inherited from <a href="#">Object</a> )                                | Determines whether the specified <a href="#">Object</a> is equal to the current <a href="#">Object</a> .                                                      |
| <a href="#">GetHashCode</a> (inherited from <a href="#">Object</a> )                           | Serves as a hash function for a particular type. <a href="#">GetHashCode</a> is suitable for use in hashing algorithms and data structures like a hash table. |
| <a href="#">GetLifetimeService</a> (inherited from <a href="#">MarshalByRefObject</a> )        | Retrieves the current lifetime service object that controls the lifetime policy for this instance.                                                            |
| <a href="#">GetType</a> (inherited from <a href="#">Object</a> )                               | Gets the <a href="#">Type</a> of the current instance.                                                                                                        |
| <a href="#">InitializeLifetimeService</a> (inherited from <a href="#">MarshalByRefObject</a> ) | Obtains a lifetime service object to control the lifetime policy for this instance.                                                                           |
| <a href="#">ToString</a>                                                                       | Overridden. Gets a string containing the <a href="#">ParameterName</a> .                                                                                      |

[MySqlParameter Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.7.1.1.3.1.1.1. [MySQLParameter](#) Constructor

Initializes a new instance of the [MySQLParameter](#) class.

#### Overload List

Initializes a new instance of the [MySQLParameter](#) class.

- [public MySQLParameter\(\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name and the data type.

- [public MySQLParameter\(string,MySQLDbType\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the [MySQLDbType](#) , and the size.

- [public MySQLParameter\(string,MySQLDbType,int\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the type of the parameter, the size of the parameter, a [ParameterDirection](#), the precision of the parameter, the scale of the parameter, the source column, a [DataRowVersion](#) to use, and the value of the parameter.

- [public MySQLParameter\(string,MySQLDbType,int,ParameterDirection,bool,byte,byte,string,DataRowVersion,object\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the [MySQLDbType](#) , the size, and the source column name.

- [public MySQLParameter\(string,MySQLDbType,int,string\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name and a value of the new [MySQLParameter](#).

- [public MySQLParameter\(string,object\);](#)

### 29.2.4.1.2.1.7.1.1.3.1.1.1.1. [MySQLParameter](#) Constructor ()

Initializes a new instance of the [MySQLParameter](#) class.

#### Syntax: Visual Basic

```
Overloads Public Sub New()
```

#### Syntax: C#

```
public MySQLParameter();
```

#### See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlCommand Namespace](#) , [MySQLParameter Constructor Overload List](#)

### 29.2.4.1.2.1.7.1.1.3.1.1.1.2. [MySQLParameter](#) Constructor

Initializes a new instance of the [MySQLParameter](#) class with the parameter name and the data type.

#### Syntax: Visual Basic

```
Overloads Public Sub New(_
```

```

ByVal parameterName As String, _
ByVal dbType As MySqlDbType _
)

```

**Syntax: C#**

```

public MySqlParameter(
string parameterName,
MySqlDbType dbType
);

```

**Parameters**

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySqlDbType](#) values.

29.2.4.1.2.1.7.1.1.3.1.1.1.2.1. [MySqlDbType](#) Enumeration

Specifies MySQL specific data type of a field, property, for use in a [MySqlParameter](#) .

**Syntax: Visual Basic**

```
Public Enum MySqlDbType
```

**Syntax: C#**

```
public enum MySqlDbType
```

**Members**

| Member Name | Description                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VarChar     | A variable-length string containing 0 to 65535 characters                                                                                                                                     |
| Timestamp   | A timestamp. The range is '1970-01-01 00:00:01' to sometime in the year 2038                                                                                                                  |
| LongBlob    | A BLOB column with a maximum length of 4294967295 or 4G (2 <sup>32</sup> - 1) characters                                                                                                      |
| Time        | The range is '-838:59:59' to '838:59:59'.                                                                                                                                                     |
| TinyBlob    | A BLOB column with a maximum length of 255 (2 <sup>8</sup> - 1) characters                                                                                                                    |
| Datetime    | The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'.                                                                                                                        |
| Decimal     | A fixed precision and scale numeric value between -1038 -1 and 1038 -1.                                                                                                                       |
| UByte       |                                                                                                                                                                                               |
| Blob        | A BLOB column with a maximum length of 65535 (2 <sup>16</sup> - 1) characters                                                                                                                 |
| Double      | A normal-size (double-precision) floating-point number. Allowable values are -1.7976931348623157E+308 to -2.2250738585072014E-308, 0, and 2.2250738585072014E-308 to 1.7976931348623157E+308. |
| Newdate     | Obsolete Use Datetime or Date type                                                                                                                                                            |
| Byte        | The signed range is -128 to 127. The unsigned range is 0 to 255.                                                                                                                              |
| Date        | Date The supported range is '1000-01-01' to '9999-12-31'.                                                                                                                                     |

|            |                                                                                                                                                                                                               |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VarChar    | A variable-length string containing 0 to 255 characters                                                                                                                                                       |
| UInt16     |                                                                                                                                                                                                               |
| UInt24     |                                                                                                                                                                                                               |
| Int16      | A 16-bit signed integer. The signed range is -32768 to 32767. The unsigned range is 0 to 65535                                                                                                                |
| NewDecimal | New Decimal                                                                                                                                                                                                   |
| Set        | A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... A SET can have a maximum of 64 members.                                |
| String     | Obsolete Use VarChar type                                                                                                                                                                                     |
| Enum       | An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special "" error value. An ENUM can have a maximum of 65535 distinct values |
| Geometry   |                                                                                                                                                                                                               |
| UInt64     |                                                                                                                                                                                                               |
| Int64      | A 64-bit signed integer.                                                                                                                                                                                      |
| UInt32     |                                                                                                                                                                                                               |
| Int24      | Specifies a 24 (3 byte) signed or unsigned value.                                                                                                                                                             |
| Bit        | Bit-field data type                                                                                                                                                                                           |
| Float      | A small (single-precision) floating-point number. Allowable values are -3.402823466E+38 to -1.175494351E-38, 0, and 1.175494351E-38 to 3.402823466E+38.                                                       |
| Year       | A year in 2- or 4-digit format (default is 4-digit). The allowable values are 1901 to 2155, 0000 in the 4-digit year format, and 1970-2069 if you use the 2-digit format (70-69)                              |
| Int32      | A 32-bit signed integer                                                                                                                                                                                       |
| MediumBlob | A BLOB column with a maximum length of 16777215 (2 <sup>24</sup> - 1) characters                                                                                                                              |

**Requirements**

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySQL.Data (in MySQL.Data.dll)

**See Also**

[MySQL.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.7.1.1.3.1.1.3. [MySQLParameter](#) Constructor (String, MySqlDbType, Int32)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the [MySqlDbType](#) , and the size.

**Syntax: Visual Basic**

```
Overloads Public Sub New(_
 ByVal parameterName As String, _
 ByVal dbType As MySqlDbType, _
 ByVal size As Integer _
)
```

**Syntax: C#**

```
public MySQLParameter(
 string parameterName,
 MySqlDbType dbType,
 int size
);
```

## Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySQLDbType](#) values.
- `size`: The length of the parameter.

## See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameter Constructor Overload List](#)

### 29.2.4.1.2.1.7.1.1.3.1.1.4. [MySQLParameter](#) Constructor

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the type of the parameter, the size of the parameter, a [ParameterDirection](#), the precision of the parameter, the scale of the parameter, the source column, a [DataRowVersion](#)to use, and the value of the parameter.

#### Syntax: Visual Basic

```
Overloads Public Sub New(_
 ByVal parameterName As String, _
 ByVal dbType As MySQLDbType, _
 ByVal size As Integer, _
 ByVal direction As ParameterDirection, _
 ByVal isNullable As Boolean, _
 ByVal precision As Byte, _
 ByVal scale As Byte, _
 ByVal sourceColumn As String, _
 ByVal sourceVersion As DataRowVersion, _
 ByVal value As Object _
)
```

#### Syntax: C#

```
public MySQLParameter(
 stringparameterName,
 MySQLDbTypedbType,
 intsize,
 ParameterDirectiondirection,
 boolisNullable,
 byteprecision,
 bytescale,
 stringsourceColumn,
 DataRowVersionsourceVersion,
 objectvalue
);
```

## Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySQLDbType](#) values.
- `size`: The length of the parameter.
- `direction`: One of the [ParameterDirection](#)values.
- `isNullable`: true if the value of the field can be null, otherwise false.
- `precision`: The total number of digits to the left and right of the decimal point to which [Value](#) is resolved.
- `scale`: The total number of decimal places to which [Value](#) is resolved.
- `sourceColumn`: The name of the source column.
- `sourceVersion`: One of the [DataRowVersion](#)values.
- `value`: An Objectthat is the value of the [MySQLParameter](#) .

## Exceptions

| Exception Type | Condition |
|----------------|-----------|
|----------------|-----------|

|                   |  |
|-------------------|--|
| ArgumentException |  |
|-------------------|--|

**See Also**

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameter Constructor Overload List](#)

## 29.2.4.1.2.1.7.1.1.3.1.1.4.1. Value Property

Gets or sets the value of the parameter.

**Syntax: Visual Basic**

```
NotOverridable Public Property Value As Object _
 Implements IDataParameter.Value
```

**Syntax: C#**

```
public object Value {get; set;}
```

**Implements**

IDataParameter.Value

**See Also**

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.7.1.1.3.1.1.5. MySQLParameter Constructor

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the [MySQLDbType](#) , the size, and the source column name.

**Syntax: Visual Basic**

```
Overloads Public Sub New(_
 ByVal parameterName As String, _
 ByVal dbType As MySQLDbType, _
 ByVal size As Integer, _
 ByVal sourceColumn As String _
)
```

**Syntax: C#**

```
public MySQLParameter(
 stringparameterName,
 MySQLDbTypedbType,
 intsize,
 stringsourceColumn
);
```

**Parameters**

- [parameterName](#): The name of the parameter to map.
- [dbType](#): One of the [MySQLDbType](#) values.
- [size](#): The length of the parameter.
- [sourceColumn](#): The name of the source column.

**See Also**

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameter Constructor Overload List](#)

## 29.2.4.1.2.1.7.1.1.3.1.1.6. MySQLParameter Constructor

Initializes a new instance of the [MySQLParameter](#) class with the parameter name and a value of the new MySQLParameter.

**Syntax: Visual Basic**

```
Overloads Public Sub New(_
 ByVal parameterName As String, _
 ByVal value As Object _
)
```

**Syntax: C#**

```
public MySqlParameter(
 string parameterName,
 object value
);
```

**Parameters**

- `parameterName`: The name of the parameter to map.
- `value`: An Object that is the value of the [MySqlParameter](#).

**See Also**

[MySqlParameter Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlParameter Constructor Overload List](#)

## 29.2.4.1.2.1.7.1.1.3.1.1.2. DbType Property

Gets or sets the DbType of the parameter.

**Syntax: Visual Basic**

```
NotOverridable Public Property DbType As DbType _
 Implements IDataParameter.DbType
```

**Syntax: C#**

```
public System.Data.DbType DbType {get; set;}
```

**Implements**

IDataParameter.DbType

**See Also**

[MySqlParameter Class](#), [MySql.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.7.1.1.3.1.1.3. Direction Property

Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice.

**Syntax: Visual Basic**

```
NotOverridable Public Property Direction As ParameterDirection _
 Implements IDataParameter.Direction
```

**Syntax: C#**

```
public System.Data.ParameterDirection Direction {get; set;}
```

**Implements**

IDataParameter.Direction

**See Also**

[MySqlParameter Class](#), [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.7.1.1.3.1.1.4. IsNullable Property

Gets or sets a value indicating whether the parameter accepts null values.

##### Syntax: Visual Basic

```
NotOverridable Public Property IsNullable As Boolean _
 Implements IDataParameter.IsNullable
```

##### Syntax: C#

```
public bool IsNullable {get; set;}
```

##### Implements

IDataParameter.IsNullable

##### See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlCommand Namespace](#)

#### 29.2.4.1.2.1.7.1.1.3.1.1.5. IsUnsigned Property

##### Syntax: Visual Basic

```
Public Property IsUnsigned As Boolean
```

##### Syntax: C#

```
public bool IsUnsigned {get; set;}
```

##### See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlCommand Namespace](#)

#### 29.2.4.1.2.1.7.1.1.3.1.1.6. MySQLDbType Property

Gets or sets the MySQLDbType of the parameter.

##### Syntax: Visual Basic

```
Public Property MySQLDbType As MySQLDbType
```

##### Syntax: C#

```
public MySQLDbType MySQLDbType {get; set;}
```

##### See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlCommand Namespace](#)

#### 29.2.4.1.2.1.7.1.1.3.1.1.7. ParameterName Property

Gets or sets the name of the MySQLParameter.

##### Syntax: Visual Basic

```
NotOverridable Public Property ParameterName As String _
 Implements IDataParameter.ParameterName
```

##### Syntax: C#

```
public string ParameterName {get; set;}
```

##### Implements

IDataParameter.ParameterName

**See Also**

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.7.1.1.3.1.1.8. Precision Property

Gets or sets the maximum number of digits used to represent the [Value](#) property.

**Syntax: Visual Basic**

```
NotOverridable Public Property Precision As Byte _
 Implements IDbDataParameter.Precision
```

**Syntax: C#**

```
public byte Precision {get; set;}
```

**Implements**

IDbDataParameter.Precision

**See Also**

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.7.1.1.3.1.1.9. Scale Property

Gets or sets the number of decimal places to which [Value](#) is resolved.

**Syntax: Visual Basic**

```
NotOverridable Public Property Scale As Byte _
 Implements IDbDataParameter.Scale
```

**Syntax: C#**

```
public byte Scale {get; set;}
```

**Implements**

IDbDataParameter.Scale

**See Also**

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.7.1.1.3.1.1.10. Size Property

Gets or sets the maximum size, in bytes, of the data within the column.

**Syntax: Visual Basic**

```
NotOverridable Public Property Size As Integer _
 Implements IDbDataParameter.Size
```

**Syntax: C#**

```
public int Size {get; set;}
```

**Implements**

IDbDataParameter.Size

**See Also**

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.7.1.1.3.1.1.11. SourceColumn Property

Gets or sets the name of the source column that is mapped to the DataSet and used for loading or returning the [Value](#) .

#### Syntax: Visual Basic

```
NotOverridable Public Property SourceColumn As String _
 Implements IDataParameter.SourceColumn
```

#### Syntax: C#

```
public string SourceColumn {get; set;}
```

#### Implements

IDataParameter.SourceColumn

#### See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.7.1.1.3.1.1.12. SourceVersion Property

Gets or sets the DataRowVersion to use when loading [Value](#) .

#### Syntax: Visual Basic

```
NotOverridable Public Property SourceVersion As DataRowVersion _
 Implements IDataParameter.SourceVersion
```

#### Syntax: C#

```
public System.Data.DataRowVersion SourceVersion {get; set;}
```

#### Implements

IDataParameter.SourceVersion

#### See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.7.1.1.3.1.1.13. MySQLParameter.ToString Method

Overridden. Gets a string containing the [ParameterName](#) .

#### Syntax: Visual Basic

```
Overrides Public Function ToString() As String
```

#### Syntax: C#

```
public override string ToString();
```

#### Return Value

#### See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.7.1.1.3.2. Item Property (Int32)

Gets the [MySQLParameter](#) at the specified index.

#### Syntax: Visual Basic

```
Overloads Public Default Property Item(_
 ByVal index As Integer _
) As MySQLParameter
```

**Syntax: C#**

```
public MySqlParameter this[
 int index
] {get; set;}
```

**See Also**

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Item Overload List](#)

## 29.2.4.1.2.1.7.1.1.3.3. Item Property (String)

Gets the [MySqlParameter](#) with the specified name.

**Syntax: Visual Basic**

```
Overloads Public Default Property Item(_
 ByVal name As String _
) As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter this[
 string name
] {get; set;}
```

**See Also**

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Item Overload List](#)

## 29.2.4.1.2.1.7.1.1.4. Add Method

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#) .

**Overload List**

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#) .

- [public MySqlParameter Add\(MySqlParameter\);](#)

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#) .

- [public int Add\(object\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the parameter name and the data type.

- [public MySqlParameter Add\(string, MySqlDbType\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, and the column length.

- [public MySqlParameter Add\(string, MySqlDbType, int\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, the column length, and the source column name.

- [public MySqlParameter Add\(string, MySqlDbType, int, string\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the specified parameter name and value.

- [public MySqlParameter Add\(string, object\);](#)

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.7.1.1.4.1. [MySQLParameterCollection.Add](#) Method

Adds the specified [MySQLParameter](#) object to the [MySQLParameterCollection](#) .

**Syntax: Visual Basic**

```
Overloads Public Function Add(_
 ByVal value As MySQLParameter _
) As MySQLParameter
```

**Syntax: C#**

```
public MySQLParameter Add(
 MySQLParametervalue
);
```

**Parameters**

- **value:** The [MySQLParameter](#) to add to the collection.

**Return Value**

The newly added [MySQLParameter](#) object.

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.Add Overload List](#)

29.2.4.1.2.1.7.1.1.4.2. [MySQLParameterCollection.Add](#) Method

Adds the specified [MySQLParameter](#) object to the [MySQLParameterCollection](#) .

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Function Add(_
 ByVal value As Object _
) As Integer _
 Implements IList.Add
```

**Syntax: C#**

```
public int Add(
 objectvalue
);
```

**Parameters**

- **value:** The [MySQLParameter](#) to add to the collection.

**Return Value**

The index of the new [MySQLParameter](#) object.

**Implements**

IList.Add

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.Add Overload List](#)

29.2.4.1.2.1.7.1.1.4.3. [MySQLParameterCollection.Add](#) Method

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) given the parameter name and the data type.

**Syntax: Visual Basic**

```
Overloads Public Function Add(_
 ByVal parameterName As String, _
 ByVal dbType As MySqlDbType _
) As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter Add(
 stringparameterName,
 MySqlDbTypedbType
);
```

**Parameters**

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySqlDbType](#) values.

**Return Value**

The newly added [MySqlParameter](#) object.

**See Also**

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

**29.2.4.1.2.1.7.1.1.4.4. [MySqlParameterCollection.Add](#) Method**

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, and the column length.

**Syntax: Visual Basic**

```
Overloads Public Function Add(_
 ByVal parameterName As String, _
 ByVal dbType As MySqlDbType, _
 ByVal size As Integer _
) As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter Add(
 stringparameterName,
 MySqlDbTypedbType,
 intsize
);
```

**Parameters**

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the column.

**Return Value**

The newly added [MySqlParameter](#) object.

**See Also**

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

**29.2.4.1.2.1.7.1.1.4.5. [MySqlParameterCollection.Add](#) Method**

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, the column length, and the source column name.

**Syntax: Visual Basic**

```
Overloads Public Function Add(_
 ByVal parameterName As String, _
 ByVal dbType As MySqlDbType, _
 ByVal size As Integer, _
 ByVal sourceColumn As String _
) As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter Add(
 stringparameterName,
 MySqlDbTypedbType,
 intsize,
 stringsourceColumn
);
```

**Parameters**

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the column.
- `sourceColumn`: The name of the source column.

**Return Value**

The newly added [MySqlParameter](#) object.

**See Also**

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

#### 29.2.4.1.2.1.7.1.1.4.6. [MySqlParameterCollection.Add](#) Method

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the specified parameter name and value.

**Syntax: Visual Basic**

```
Overloads Public Function Add(_
 ByVal parameterName As String, _
 ByVal value As Object _
) As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter Add(
 stringparameterName,
 objectvalue
);
```

**Parameters**

- `parameterName`: The name of the parameter.
- `value`: The [Value](#) of the [MySqlParameter](#) to add to the collection.

**Return Value**

The newly added [MySqlParameter](#) object.

**See Also**

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

#### 29.2.4.1.2.1.7.1.1.5. [MySqlParameterCollection.Clear](#) Method

Removes all items from the collection.

**Syntax: Visual Basic**

```
NotOverridable Public Sub Clear() _
 Implements IList.Clear
```

**Syntax: C#**

```
public void Clear();
```

**Implements**

IList.Clear

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.2.1.7.1.1.6. Contains Method**

Gets a value indicating whether a [MySQLParameter](#) exists in the collection.

**Overload List**

Gets a value indicating whether a [MySQLParameter](#) exists in the collection.

- `public bool Contains(object);`

Gets a value indicating whether a [MySQLParameter](#) with the specified parameter name exists in the collection.

- `public bool Contains(string);`

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.2.1.7.1.1.6.1. MySQLParameterCollection.Contains Method**

Gets a value indicating whether a [MySQLParameter](#) exists in the collection.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Function Contains(_
 ByVal value As Object _
) As Boolean _
 Implements IList.Contains
```

**Syntax: C#**

```
public bool Contains(
 object value
);
```

**Parameters**

- `value`: The value of the [MySQLParameter](#) object to find.

**Return Value**

true if the collection contains the [MySQLParameter](#) object; otherwise, false.

**Implements**

IList.Contains

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.Contains Overload List](#)

29.2.4.1.2.1.7.1.1.6.2. [MySQLParameterCollection.Contains](#) Method

Gets a value indicating whether a [MySQLParameter](#) with the specified parameter name exists in the collection.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Function Contains(_
 ByVal name As String _
) As Boolean _
- Implements IDataParameterCollection.Contains
```

**Syntax: C#**

```
public bool Contains(
 stringname
);
```

**Parameters**

- **name**: The name of the [MySQLParameter](#) object to find.

**Return Value**

true if the collection contains the parameter; otherwise, false.

**Implements**

[IDataParameterCollection.Contains](#)

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.Contains Overload List](#)

29.2.4.1.2.1.7.1.1.7. [MySQLParameterCollection.CopyTo](#) Method

Copies [MySQLParameter](#) objects from the [MySQLParameterCollection](#) to the specified array.

**Syntax: Visual Basic**

```
NotOverridable Public Sub CopyTo(_
 ByVal array As Array, _
 ByVal index As Integer _
) _
- Implements ICollection.CopyTo
```

**Syntax: C#**

```
public void CopyTo(
 Arrayarray,
 intindex
);
```

**Parameters**

- **array**:
- **index**:

**Implements**

[ICollection.CopyTo](#)

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.7.1.1.8. IndexOf Method

Gets the location of a [MySQLParameter](#) in the collection.

##### Overload List

Gets the location of a [MySQLParameter](#) in the collection.

- `public int IndexOf(object);`

Gets the location of the [MySQLParameter](#) in the collection with a specific parameter name.

- `public int IndexOf(string);`

##### See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.7.1.1.8.1. [MySQLParameterCollection.IndexOf](#) Method

Gets the location of a [MySQLParameter](#) in the collection.

##### Syntax: Visual Basic

```
NotOverridable Overloads Public Function IndexOf(_
 ByVal value As Object _
) As Integer _
- Implements IList.IndexOf
```

##### Syntax: C#

```
public int IndexOf(
 objectvalue
);
```

##### Parameters

- `value`: The [MySQLParameter](#) object to locate.

##### Return Value

The zero-based location of the [MySQLParameter](#) in the collection.

##### Implements

[IList.IndexOf](#)

##### See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.IndexOf Overload List](#)

#### 29.2.4.1.2.1.7.1.1.8.2. [MySQLParameterCollection.IndexOf](#) Method

Gets the location of the [MySQLParameter](#) in the collection with a specific parameter name.

##### Syntax: Visual Basic

```
NotOverridable Overloads Public Function IndexOf(_
 ByVal parameterName As String _
) As Integer _
- Implements IDataParameterCollection.IndexOf
```

##### Syntax: C#

```
public int IndexOf(
string parameterName
)
```

### Parameters

- `parameterName`: The name of the [MySQLParameter](#) object to retrieve.

### Return Value

The zero-based location of the [MySQLParameter](#) in the collection.

### Implements

[IDataParameterCollection.IndexOf](#)

### See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLParameterCollection.IndexOf Overload List](#)

#### 29.2.4.1.2.1.7.1.1.9. [MySQLParameterCollection.Insert](#) Method

Inserts a [MySQLParameter](#) into the collection at the specified index.

### Syntax: Visual Basic

```
NotOverridable Public Sub Insert(_
 ByVal index As Integer, _
 ByVal value As Object _
) _
- Implements IList.Insert
```

### Syntax: C#

```
public void Insert(
int index,
object value
)
```

### Parameters

- `index`:
- `value`:

### Implements

[IList.Insert](#)

### See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.7.1.1.10. [MySQLParameterCollection.Remove](#) Method

Removes the specified [MySQLParameter](#) from the collection.

### Syntax: Visual Basic

```
NotOverridable Public Sub Remove(_
 ByVal value As Object _
) _
- Implements IList.Remove
```

### Syntax: C#

```
public void Remove(
object value
)
```

**Parameters**

- `value`:

**Implements**

`IList.Remove`

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.2.1.7.1.1.11. RemoveAt Method**

Removes the specified [MySQLParameter](#) from the collection.

**Overload List**

Removes the specified [MySQLParameter](#) from the collection using a specific index.

- `public void RemoveAt(int);`

Removes the specified [MySQLParameter](#) from the collection using the parameter name.

- `public void RemoveAt(string);`

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.2.1.7.1.1.11.1. MySQLParameterCollection.RemoveAt Method**

Removes the specified [MySQLParameter](#) from the collection using a specific index.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Sub RemoveAt(_
 ByVal index As Integer _
) _
- Implements IList.RemoveAt
```

**Syntax: C#**

```
public void RemoveAt(
 int index
);
```

**Parameters**

- `index`: The zero-based index of the parameter.

**Implements**

`IList.RemoveAt`

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.RemoveAt Overload List](#)

**29.2.4.1.2.1.7.1.1.11.2. MySQLParameterCollection.RemoveAt Method**

Removes the specified [MySQLParameter](#) from the collection using the parameter name.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Sub RemoveAt(_
 ByVal name As String _
) _
- Implements IDataParameterCollection.RemoveAt
```

**Syntax: C#**

```
public void RemoveAt(
 string name
);
```

**Parameters**

- **name**: The name of the [MySQLParameter](#) object to retrieve.

**Implements**

[IDataParameterCollection.RemoveAt](#)

**See Also**

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.RemoveAt Overload List](#)

## 29.2.4.1.2.1.8. Transaction Property

**Syntax: Visual Basic**

```
Public Property Transaction As MySQLTransaction
```

**Syntax: C#**

```
public MySQLTransaction Transaction {get; set;}
```

**See Also**

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.9. UpdatedRowSource Property

**Syntax: Visual Basic**

```
NotOverridable Public Property UpdatedRowSource As UpdateRowSource _
- Implements IDbCommand.UpdatedRowSource
```

**Syntax: C#**

```
public System.Data.UpdateRowSource UpdatedRowSource {get; set;}
```

**Implements**

[IDbCommand.UpdatedRowSource](#)

**See Also**

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.10. [MySQLCommand.Cancel](#) Method

Attempts to cancel the execution of a [MySQLCommand](#). This operation is not supported.

**Syntax: Visual Basic**

```
NotOverridable Public Sub Cancel() _
- Implements IDbCommand.Cancel
```

**Syntax: C#**

```
public void Cancel();
```

**Implements**

IDbCommand.Cancel

**Remarks**

Cancelling an executing command is currently not supported on any version of MySQL.

**Exceptions**

| Exception Type        | Condition                        |
|-----------------------|----------------------------------|
| NotSupportedException | This operation is not supported. |

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.11.  [MySqlCommand.CreateParameter](#) Method

Creates a new instance of a  [MySqlParameter](#) object.

**Syntax: Visual Basic**

```
Public Function CreateParameter() As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter CreateParameter();
```

**Return Value**

A  [MySqlParameter](#) object.

**Remarks**

This method is a strongly-typed version of CreateParameter.

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.12.  [MySqlCommand.ExecuteNonQuery](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function ExecuteNonQuery() As Integer _
 Implements IDbCommand.ExecuteNonQuery
```

**Syntax: C#**

```
public int ExecuteNonQuery();
```

**Implements**

IDbCommand.ExecuteNonQuery

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.13. ExecuteReader Method

**Overload List**

- [public MySQLDataReader ExecuteReader\(\);](#)
- [public MySQLDataReader ExecuteReader\(CommandBehavior\);](#)

**See Also**

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.13.1. [MySQLCommand.ExecuteReader](#) Method**Syntax: Visual Basic**

```
Overloads Public Function ExecuteReader() As MySQLDataReader
```

**Syntax: C#**

```
public MySQLDataReader ExecuteReader();
```

**See Also**

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLCommand.ExecuteReader Overload List](#)

29.2.4.1.2.1.13.1.1. [MySQLDataReader](#) Class

Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.

For a list of all members of this type, see [MySQLDataReader Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySQLDataReader_
 Inherits MarshalByRefObject_
 Implements IEnumerable, IDataReader, IDisposable, IDataRecord
```

**Syntax: C#**

```
public sealed class MySQLDataReader : MarshalByRefObject, IEnumerable, IDataReader, IDisposable, IDataRecord
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySQL.Data (in MySQL.Data.dll)

**See Also**

[MySQLDataReader Members](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.13.1.1.1. [MySQLDataReader](#) Members

**Public Instance Properties**

|                            |                                                                                                                                |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Depth</a>      | Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0. |
| <a href="#">FieldCount</a> | Gets the number of columns in the current row.                                                                                 |
| <a href="#">HasRows</a>    | Gets a value indicating whether the MySQLDataReader contains one or more rows.                                                 |
| <a href="#">IsClosed</a>   | Gets a value indicating whether the data reader is closed.                                                                     |
| <a href="#">Item</a>       | Overloaded. Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the           |

|                                 |                                                                                          |
|---------------------------------|------------------------------------------------------------------------------------------|
|                                 | MySqlDataReader class.                                                                   |
| <a href="#">RecordsAffected</a> | Gets the number of rows changed, inserted, or deleted by execution of the SQL statement. |

**Public Instance Methods**

|                                                                               |                                                                                                                                               |
|-------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Close</a>                                                         | Closes the MySqlDataReader object.                                                                                                            |
| <a href="#">CreateObjRef</a> (inherited from MarshalByRefObject)              | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.           |
| <a href="#">Equals</a> (inherited from Object)                                | Determines whether the specified Object is equal to the current Object.                                                                       |
| <a href="#">GetBoolean</a>                                                    | Gets the value of the specified column as a Boolean.                                                                                          |
| <a href="#">GetByte</a>                                                       | Gets the value of the specified column as a byte.                                                                                             |
| <a href="#">GetBytes</a>                                                      | Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.                        |
| <a href="#">GetChar</a>                                                       | Gets the value of the specified column as a single character.                                                                                 |
| <a href="#">GetChars</a>                                                      | Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.                |
| <a href="#">GetDataTypeName</a>                                               | Gets the name of the source data type.                                                                                                        |
| <a href="#">GetDateTime</a>                                                   |                                                                                                                                               |
| <a href="#">GetDecimal</a>                                                    |                                                                                                                                               |
| <a href="#">GetDouble</a>                                                     |                                                                                                                                               |
| <a href="#">GetFieldType</a>                                                  | Gets the Type that is the data type of the object.                                                                                            |
| <a href="#">GetFloat</a>                                                      |                                                                                                                                               |
| <a href="#">GetGuid</a>                                                       |                                                                                                                                               |
| <a href="#">GetHashCode</a> (inherited from Object)                           | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| <a href="#">GetInt16</a>                                                      |                                                                                                                                               |
| <a href="#">GetInt32</a>                                                      |                                                                                                                                               |
| <a href="#">GetInt64</a>                                                      |                                                                                                                                               |
| <a href="#">GetLifetimeService</a> (inherited from MarshalByRefObject)        | Retrieves the current lifetime service object that controls the lifetime policy for this instance.                                            |
| <a href="#">GetMySqlDateTime</a>                                              |                                                                                                                                               |
| <a href="#">GetName</a>                                                       | Gets the name of the specified column.                                                                                                        |
| <a href="#">GetOrdinal</a>                                                    | Gets the column ordinal, given the name of the column.                                                                                        |
| <a href="#">GetSchemaTable</a>                                                | Returns a DataTable that describes the column metadata of the MySqlDataReader.                                                                |
| <a href="#">GetString</a>                                                     |                                                                                                                                               |
| <a href="#">GetTimeSpan</a>                                                   |                                                                                                                                               |
| <a href="#">GetType</a> (inherited from Object)                               | Gets the Type of the current instance.                                                                                                        |
| <a href="#">GetUInt16</a>                                                     |                                                                                                                                               |
| <a href="#">GetUInt32</a>                                                     |                                                                                                                                               |
| <a href="#">GetUInt64</a>                                                     |                                                                                                                                               |
| <a href="#">GetValue</a>                                                      | Gets the value of the specified column in its native format.                                                                                  |
| <a href="#">GetValues</a>                                                     | Gets all attribute columns in the collection for the current row.                                                                             |
| <a href="#">InitializeLifetimeService</a> (inherited from MarshalByRefObject) | Obtains a lifetime service object to control the lifetime policy for this instance.                                                           |
| <a href="#">IsDBNull</a>                                                      | Gets a value indicating whether the column contains non-existent or missing values.                                                           |
| <a href="#">NextResult</a>                                                    | Advances the data reader to the next result, when reading the results of batch SQL statements.                                                |

|                                                 |                                                      |
|-------------------------------------------------|------------------------------------------------------|
| <a href="#">Read</a>                            | Advances the MySQLDataReader to the next record.     |
| <a href="#">ToString(inherited from Object)</a> | Returns a String that represents the current Object. |

## 29.2.4.1.2.1.13.1.1.1.1. Depth Property

Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property Depth As Integer _
 Implements IDataReader.Depth
```

**Syntax: C#**

```
public int Depth {get;}
```

**Implements**

IDataReader.Depth

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.13.1.1.1.2. FieldCount Property

Gets the number of columns in the current row.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property FieldCount As Integer _
 Implements IDataRecord.FieldCount
```

**Syntax: C#**

```
public int FieldCount {get;}
```

**Implements**

IDataRecord.FieldCount

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.13.1.1.1.3. HasRows Property

Gets a value indicating whether the MySQLDataReader contains one or more rows.

**Syntax: Visual Basic**

```
Public ReadOnly Property HasRows As Boolean
```

**Syntax: C#**

```
public bool HasRows {get;}
```

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 29.2.4.1.2.1.13.1.1.1.4. IsClosed Property

Gets a value indicating whether the data reader is closed.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property IsClosed As Boolean _
 Implements IDataReader.IsClosed
```

**Syntax: C#**

```
public bool IsClosed {get;}
```

**Implements**

IDataReader.IsClosed

**See Also**

[MySQLDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.13.1.1.1.5. Item Property

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

**Overload List**

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

- [public object this\[int\] {get;}](#)

Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

- [public object this\[string\] {get;}](#)

**See Also**

[MySQLDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.13.1.1.1.5.1. Item Property (Int32)

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Default ReadOnly Property Item(_
 ByVal i As Integer _
) _
 Implements IDataRecord.Item As Object _
 Implements IDataRecord.Item
```

**Syntax: C#**

```
public object this[
 inti
] {get;}
```

**Implements**

IDataRecord.Item

**See Also**

[MySQLDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySQLDataReader.Item Overload List](#)

#### 29.2.4.1.2.1.13.1.1.1.5.2. Item Property (String)

Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Default ReadOnly Property Item(_
 ByVal name As String _
) _
- Implements IDataRecord.Item As Object _
- Implements IDataRecord.Item
```

**Syntax: C#**

```
public object this[
 string name
] {get;}
```

**Implements**

IDataRecord.Item

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLDataReader.Item Overload List](#)

**29.2.4.1.2.1.13.1.1.1.6. RecordsAffected Property**

Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property RecordsAffected As Integer _
- Implements IDataReader.RecordsAffected
```

**Syntax: C#**

```
public int RecordsAffected {get;}
```

**Implements**

IDataReader.RecordsAffected

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.2.1.13.1.1.1.7. MySQLDataReader.Close Method**

Closes the MySQLDataReader object.

**Syntax: Visual Basic**

```
NotOverridable Public Sub Close() _
- Implements IDataReader.Close
```

**Syntax: C#**

```
public void Close();
```

**Implements**

IDataReader.Close

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.2.1.13.1.1.1.8. MySQLDataReader.GetBoolean Method**

Gets the value of the specified column as a Boolean.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetBoolean(_
 ByVal i As Integer _
) As Boolean _
 Implements IDataRecord.GetBoolean
```

**Syntax: C#**

```
public bool GetBoolean(
 inti
);
```

**Parameters**

- `i`:

**Return Value****Implements**

IDataRecord.GetBoolean

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.13.1.1.1.9. [MySqlDataReader.GetByte](#) Method

Gets the value of the specified column as a byte.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetByte(_
 ByVal i As Integer _
) As Byte _
 Implements IDataRecord.GetByte
```

**Syntax: C#**

```
public byte GetByte(
 inti
);
```

**Parameters**

- `i`:

**Return Value****Implements**

IDataRecord.GetByte

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.13.1.1.1.10. [MySqlDataReader.GetBytes](#) Method

Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetBytes(_
 ByVal i As Integer, _
 ByVal dataIndex As Long, _
 ByVal buffer As Byte(), _
 ByVal bufferIndex As Integer, _
```

```

 ByVal length As Integer _
) As Long _
- Implements IDataRecord.GetBytes

```

**Syntax: C#**

```

public long GetBytes(
 inti,
 longdataIndex,
 byte[]buffer,
 intbufferIndex,
 intlength
);

```

**Parameters**

- **i**: The zero-based column ordinal.
- **dataIndex**: The index within the field from which to begin the read operation.
- **buffer**: The buffer into which to read the stream of bytes.
- **bufferIndex**: The index for buffer to begin the read operation.
- **length**: The maximum length to copy into the buffer.

**Return Value**

The actual number of bytes read.

**Implements**

IDataRecord.GetBytes

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.13.1.1.11. [MySqlDataReader.GetChar](#) Method

Gets the value of the specified column as a single character.

**Syntax: Visual Basic**

```

NotOverridable Public Function GetChar(_
 ByVal i As Integer _
) As Char _
- Implements IDataRecord.GetChar

```

**Syntax: C#**

```

public char GetChar(
 inti
);

```

**Parameters**

- **i**:

**Return Value****Implements**

IDataRecord.GetChar

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.13.1.1.12. [MySQLDataReader.GetChars](#) Method

Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.

#### Syntax: Visual Basic

```
NotOverridable Public Function GetChars(_
 ByVal i As Integer, _
 ByVal fieldOffset As Long, _
 ByVal buffer As Char(), _
 ByVal bufferoffset As Integer, _
 ByVal length As Integer _
) As Long _
- Implements IDataRecord.GetChars
```

#### Syntax: C#

```
public long GetChars(
 inti,
 longfieldOffset,
 char[]buffer,
 intbufferoffset,
 intlength
);
```

#### Parameters

- `i`:
- `fieldOffset`:
- `buffer`:
- `bufferoffset`:
- `length`:

#### Return Value

#### Implements

`IDataRecord.GetChars`

#### See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.13.1.1.13. [MySQLDataReader.GetDataTypeName](#) Method

Gets the name of the source data type.

#### Syntax: Visual Basic

```
NotOverridable Public Function GetDataTypeName(_
 ByVal i As Integer _
) As String _
- Implements IDataRecord.GetDataTypeName
```

#### Syntax: C#

```
public string GetDataTypeName(
 inti
);
```

#### Parameters

- `i`:

#### Return Value

**Implements**

IDataRecord.GetDataTypeName

**See Also**[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)29.2.4.1.2.1.13.1.1.14. [MySqlDataReader.GetDateTime](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetDateTime(_
 ByVal index As Integer _
) As Date _
- Implements IDataRecord.GetDateTime
```

**Syntax: C#**

```
public DateTime GetDateTime(
 int index
);
```

**Implements**

IDataRecord.GetDateTime

**See Also**[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)29.2.4.1.2.1.13.1.1.15. [MySqlDataReader.GetDecimal](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetDecimal(_
 ByVal index As Integer _
) As Decimal _
- Implements IDataRecord.GetDecimal
```

**Syntax: C#**

```
public decimal GetDecimal(
 int index
);
```

**Implements**

IDataRecord.GetDecimal

**See Also**[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)29.2.4.1.2.1.13.1.1.16. [MySqlDataReader.GetDouble](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetDouble(_
 ByVal index As Integer _
) As Double _
- Implements IDataRecord.GetDouble
```

**Syntax: C#**

```
public double GetDouble(
 int index
);
```

**Implements**

IDataRecord.GetDouble

#### See Also

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.13.1.1.17. [MySqlDataReader.GetFieldType](#) Method

Gets the Type that is the data type of the object.

#### Syntax: Visual Basic

```
NotOverridable Public Function GetFieldType(_
 ByVal i As Integer _
) As Type _
- Implements IDataRecord.GetFieldType
```

#### Syntax: C#

```
public Type GetFieldType(
 int i
);
```

#### Parameters

- `i`:

#### Return Value

#### Implements

IDataRecord.GetFieldType

#### See Also

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.13.1.1.18. [MySqlDataReader.GetFloat](#) Method

#### Syntax: Visual Basic

```
NotOverridable Public Function GetFloat(_
 ByVal index As Integer _
) As Single _
- Implements IDataRecord.GetFloat
```

#### Syntax: C#

```
public float GetFloat(
 int index
);
```

#### Implements

IDataRecord.GetFloat

#### See Also

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.13.1.1.19. [MySqlDataReader.GetGuid](#) Method

#### Syntax: Visual Basic

```
NotOverridable Public Function GetGuid(_
 ByVal index As Integer _
) As Guid _
- Implements IDataRecord.GetGuid
```

**Syntax: C#**

```
public Guid GetGuid(
 int index
);
```

**Implements**

IDataRecord.GetGuid

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.13.1.1.1.20. [MySQLDataReader.GetInt16](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetInt16(_
 ByVal index As Integer _
) As Short _
 Implements IDataRecord.GetInt16
```

**Syntax: C#**

```
public short GetInt16(
 int index
);
```

**Implements**

IDataRecord.GetInt16

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.13.1.1.1.21. [MySQLDataReader.GetInt32](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetInt32(_
 ByVal index As Integer _
) As Integer _
 Implements IDataRecord.GetInt32
```

**Syntax: C#**

```
public int GetInt32(
 int index
);
```

**Implements**

IDataRecord.GetInt32

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.13.1.1.1.22. [MySQLDataReader.GetInt64](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetInt64(_
 ByVal index As Integer _
) As Long _
 Implements IDataRecord.GetInt64
```

**Syntax: C#**

```
public long GetInt64(
 int index
);
```

**Implements**

IDataRecord.GetInt64

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.13.1.1.1.23. [MySqlDataReader.GetInt64](#) Method**Syntax: Visual Basic**

```
Public Function GetInt64(_
 ByVal index As Integer _
) As Int64
```

**Syntax: C#**

```
public Int64 GetInt64(
 int index
);
```

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.13.1.1.1.24. [MySqlDataReader.GetName](#) Method

Gets the name of the specified column.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetName(_
 ByVal i As Integer _
) As String _
 Implements IDataRecord.GetName
```

**Syntax: C#**

```
public string GetName(
 int i
);
```

**Parameters**

- **i**:

**Return Value****Implements**

IDataRecord.GetName

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

29.2.4.1.2.1.13.1.1.1.25. [MySqlDataReader.GetOrdinal](#) Method

Gets the column ordinal, given the name of the column.

**Syntax: Visual Basic**

```
NotOverridable Public Function.GetOrdinal(_
 ByVal name As String _
) As Integer _
 Implements IDataRecord.GetOrdinal
```

---

Implements `IDataRecord.GetOrdinal`

**Syntax: C#**

```
public int GetOrdinal(
 string name
);
```

**Parameters**

- `name`:

**Return Value****Implements**

`IDataRecord.GetOrdinal`

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.13.1.1.1.26. `MySQLDataReader.GetSchemaTable` Method

Returns a `DataTable` that describes the column metadata of the `MySQLDataReader`.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetSchemaTable() As DataTable _
 Implements IDataReader.GetSchemaTable
```

**Syntax: C#**

```
public DataTable GetSchemaTable();
```

**Return Value****Implements**

`IDataReader.GetSchemaTable`

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.13.1.1.1.27. `MySQLDataReader.GetString` Method

**Syntax: Visual Basic**

```
NotOverridable Public Function GetString(_
 ByVal index As Integer _
) As String _
 Implements IDataRecord.GetString
```

**Syntax: C#**

```
public string GetString(
 int index
);
```

**Implements**

`IDataRecord.GetString`

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

---

#### 29.2.4.1.2.1.13.1.1.1.28. [MySqlDataReader.GetTimeSpan](#) Method

**Syntax: Visual Basic**

```
Public Function GetTimeSpan(_
 ByVal index As Integer _
) As TimeSpan
```

**Syntax: C#**

```
public TimeSpan GetTimeSpan(
 int index
);
```

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.13.1.1.1.29. [MySqlDataReader.GetUInt16](#) Method

**Syntax: Visual Basic**

```
Public Function GetUInt16(_
 ByVal index As Integer _
) As UInt16
```

**Syntax: C#**

```
public ushort GetUInt16(
 int index
);
```

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.13.1.1.1.30. [MySqlDataReader.GetUInt32](#) Method

**Syntax: Visual Basic**

```
Public Function GetUInt32(_
 ByVal index As Integer _
) As UInt32
```

**Syntax: C#**

```
public uint GetUInt32(
 int index
);
```

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.13.1.1.1.31. [MySqlDataReader.GetUInt64](#) Method

**Syntax: Visual Basic**

```
Public Function GetUInt64(_
 ByVal index As Integer _
) As UInt64
```

**Syntax: C#**

```
public ulong GetUInt64(
 int index
);
```

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.13.1.1.1.32. [MySqlDataReader.GetValue](#) Method

Gets the value of the specified column in its native format.

#### Syntax: Visual Basic

```
NotOverridable Public Function GetValue(_
 ByVal i As Integer _
) As Object _
 Implements IDataRecord.GetValue
```

#### Syntax: C#

```
public object GetValue(
 inti
);
```

#### Parameters

- `i`:

#### Return Value

#### Implements

`IDataRecord.GetValue`

#### See Also

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.13.1.1.1.33. [MySqlDataReader.GetValues](#) Method

Gets all attribute columns in the collection for the current row.

#### Syntax: Visual Basic

```
NotOverridable Public Function GetValues(_
 ByVal values As Object() _
) As Integer _
 Implements IDataRecord.GetValues
```

#### Syntax: C#

```
public int GetValues(
 object[] values
);
```

#### Parameters

- `values`:

#### Return Value

#### Implements

`IDataRecord.GetValues`

#### See Also

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 29.2.4.1.2.1.13.1.1.1.34. [MySqlDataReader.IsDBNull](#) Method

Gets a value indicating whether the column contains non-existent or missing values.

#### Syntax: Visual Basic

```
NotOverridable Public Function IsDBNull(_
 ByVal i As Integer _
) As Boolean _
- Implements IDataRecord.IsDBNull
```

**Syntax: C#**

```
public bool IsDBNull(
 inti
);
```

**Parameters**

- `i`:

**Return Value****Implements**

IDataRecord.IsDBNull

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.13.1.1.1.35. [MySQLDataReader.NextResult](#) Method

Advances the data reader to the next result, when reading the results of batch SQL statements.

**Syntax: Visual Basic**

```
NotOverridable Public Function NextResult() As Boolean _
- Implements IDataReader.NextResult
```

**Syntax: C#**

```
public bool NextResult();
```

**Return Value****Implements**

IDataReader.NextResult

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

#### 29.2.4.1.2.1.13.1.1.1.36. [MySQLDataReader.Read](#) Method

Advances the MySQLDataReader to the next record.

**Syntax: Visual Basic**

```
NotOverridable Public Function Read() As Boolean _
- Implements IDataReader.Read
```

**Syntax: C#**

```
public bool Read();
```

**Return Value****Implements**

IDataReader.Read

**See Also**

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.2.1.13.2. [MySQLCommand.ExecuteReader](#) Method****Syntax: Visual Basic**

```
Overloads Public Function ExecuteReader(_
 ByVal behavior As CommandBehavior _
) As MySQLDataReader
```

**Syntax: C#**

```
public MySQLDataReader ExecuteReader(
 CommandBehaviorbehavior
);
```

**See Also**

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLCommand.ExecuteReader Overload List](#)

**29.2.4.1.2.1.14. [MySQLCommand.ExecuteScalar](#) Method****Syntax: Visual Basic**

```
NotOverridable Public Function ExecuteScalar() As Object _
 Implements IDbCommand.ExecuteScalar
```

**Syntax: C#**

```
public object ExecuteScalar();
```

**Implements**

IDbCommand.ExecuteScalar

**See Also**

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.2.1.15. [MySQLCommand.Prepare](#) Method****Syntax: Visual Basic**

```
NotOverridable Public Sub Prepare() _
 Implements IDbCommand.Prepare
```

**Syntax: C#**

```
public void Prepare();
```

**Implements**

IDbCommand.Prepare

**See Also**

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.3. [MySQLCommandBuilder](#) Class**

For a list of all members of this type, see [MySQLCommandBuilder Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySQLCommandBuilder_
 Inherits Component
```

**Syntax: C#**

```
public sealed class MySqlCommandBuilder : Component
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

[MySqlCommandBuilder Members](#) , [MySql.Data.MySqlClient Namespace](#)

**29.2.4.1.3.1. MySqlCommandBuilder Members**

[MySqlCommandBuilder overview](#)

**Public Static (Shared) Methods**

|                                  |                                                                                                                                                                                                                                                                              |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DeriveParameters</a> | Overloaded. Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL. |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Public Instance Constructors**

|                                     |                                                                          |
|-------------------------------------|--------------------------------------------------------------------------|
| <a href="#">MySqlCommandBuilder</a> | Overloaded. Initializes a new instance of the MySqlCommandBuilder class. |
|-------------------------------------|--------------------------------------------------------------------------|

**Public Instance Properties**

|                                     |                                                  |
|-------------------------------------|--------------------------------------------------|
| Container(inherited from Component) | Gets the IContainer that contains the Component. |
| <a href="#">DataAdapter</a>         |                                                  |
| <a href="#">QuotePrefix</a>         |                                                  |
| <a href="#">QuoteSuffix</a>         |                                                  |
| Site(inherited from Component)      | Gets or sets the ISite of the Component.         |

**Public Instance Methods**

|                                                       |                                                                                                                                               |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| CreateObjRef(inherited from MarshalByRefObject)       | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.           |
| Dispose(inherited from Component)                     | Releases all resources used by the Component.                                                                                                 |
| Equals(inherited from Object)                         | Determines whether the specified Object is equal to the current Object.                                                                       |
| <a href="#">GetDeleteCommand</a>                      |                                                                                                                                               |
| GetHashCode(inherited from Object)                    | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| <a href="#">GetInsertCommand</a>                      |                                                                                                                                               |
| GetLifetimeService(inherited from MarshalByRefObject) | Retrieves the current lifetime service object that controls the lifetime policy for this instance.                                            |
| GetType(inherited from Object)                        | Gets the Type of the current instance.                                                                                                        |
| <a href="#">GetUpdateCommand</a>                      |                                                                                                                                               |

|                                                              |                                                                                                      |
|--------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| InitializeLifetimeService(inherited from MarshalByRefObject) | Obtains a lifetime service object to control the lifetime policy for this instance.                  |
| <a href="#">RefreshSchema</a>                                |                                                                                                      |
| ToString(inherited from Component)                           | Returns a String containing the name of the Component, if any. This method should not be overridden. |

**Public Instance Events**

|                                    |                                                                         |
|------------------------------------|-------------------------------------------------------------------------|
| Disposed(inherited from Component) | Adds an event handler to listen to the Disposed event on the component. |
|------------------------------------|-------------------------------------------------------------------------|

**See Also**

[MySQLCommandBuilder Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.3.1.1. DeriveParameters Method**

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

**Overload List**

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

- `public static void DeriveParameters(MySqlCommand);`
- `public static void DeriveParameters(MySqlCommand,bool);`

**See Also**

[MySQLCommandBuilder Class](#) , [MySQL.Data.MySqlClient Namespace](#)

**29.2.4.1.3.1.1.1. MySqlCommandBuilder.DeriveParameters Method**

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

**Syntax: Visual Basic**

```
Overloads Public Shared Sub DeriveParameters(_
 ByVal command As MySqlCommand _
)
```

**Syntax: C#**

```
public static void DeriveParameters(
 MySqlCommand command
);
```

**Parameters**

- `command`: The MySqlCommand referencing the stored procedure from which the parameter information is to be derived. The derived parameters are added to the Parameters collection of the MySqlCommand.

**Exceptions**

| Exception Type            | Condition                                              |
|---------------------------|--------------------------------------------------------|
| InvalidOperationException | The command text is not a valid stored procedure name. |

|-------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AcceptChangesDuringFill</a> (inherited from <a href="#">DataAdapter</a> )     | Gets or sets a value indicating whether <a href="#">AcceptChanges</a> is called on a <a href="#">DataRow</a> after it is added to the <a href="#">DataTable</a> during any of the <a href="#">Fill</a> operations. |
| <a href="#">AcceptChangesDuringUpdate</a> (inherited from <a href="#">DataAdapter</a> )   | Gets or sets whether <a href="#">AcceptChanges</a> is called during a <a href="#">Update</a> .                                                                                                                     |
| <a href="#">Container</a> (inherited from <a href="#">Component</a> )                     | Gets the <a href="#">IContainer</a> that contains the <a href="#">Component</a> .                                                                                                                                  |
| <a href="#">ContinueUpdateOnError</a> (inherited from <a href="#">DataAdapter</a> )       | Gets or sets a value that specifies whether to generate an exception when an error is encountered during a row update.                                                                                             |
| <a href="#">DeleteCommand</a>                                                             | Overloaded.                                                                                                                                                                                                        |
| <a href="#">FillLoadOption</a> (inherited from <a href="#">DataAdapter</a> )              | Gets or sets the <a href="#">LoadOption</a> that determines how the adapter fills the <a href="#">DataTable</a> from the <a href="#">DbDataReader</a> .                                                            |
| <a href="#">InsertCommand</a>                                                             | Overloaded.                                                                                                                                                                                                        |
| <a href="#">MissingMappingAction</a> (inherited from <a href="#">DataAdapter</a> )        | Determines the action to take when incoming data does not have a matching table or column.                                                                                                                         |
| <a href="#">MissingSchemaAction</a> (inherited from <a href="#">DataAdapter</a> )         | Determines the action to take when existing <a href="#">DataSet</a> schema does not match incoming data.                                                                                                           |
| <a href="#">ReturnProviderSpecificTypes</a> (inherited from <a href="#">DataAdapter</a> ) | Gets or sets whether the <a href="#">Fill</a> method should return provider-specific values or common CLS-compliant values.                                                                                        |

|                                               |                                                                                                                                               |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SelectCommand</a>                 | Overloaded.                                                                                                                                   |
| Site(inherited from Component)                | Gets or sets the ISite of the Component.                                                                                                      |
| TableMappings(inherited from DataAdapter)     | Gets a collection that provides the master mapping between a source table and a DataTable.                                                    |
| UpdateBatchSize(inherited from DbDataAdapter) | Gets or sets a value that enables or disables batch processing support, and specifies the number of commands that can be executed in a batch. |
| <a href="#">UpdateCommand</a>                 | Overloaded.                                                                                                                                   |

### Public Instance Methods

|                                                                    |                                                                                                                                                   |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| CreateObjRef(inherited from MarshalByRefObject)                    | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.               |
| Dispose(inherited from Component)                                  | Releases all resources used by the Component.                                                                                                     |
| Equals(inherited from Object)                                      | Determines whether the specified Object is equal to the current Object.                                                                           |
| Fill(inherited from DbDataAdapter)                                 | Overloaded. Adds or refreshes rows in the DataSet to match those in the data source using the DataSetname, and creates a DataTable named "Table." |
| FillSchema(inherited from DbDataAdapter)                           | Overloaded. Configures the schema of the specified DataTable based on the specified SchemaType.                                                   |
| GetFillParameters(inherited from DbDataAdapter)                    | Gets the parameters set by the user when executing an SQL <a href="#">SELECT</a> statement.                                                       |
| GetHashCode(inherited from Object)                                 | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.     |
| GetLifetimeService(inherited from MarshalByRefObject)              | Retrieves the current lifetime service object that controls the lifetime policy for this instance.                                                |
| GetType(inherited from Object)                                     | Gets the Type of the current instance.                                                                                                            |
| InitializeLifetimeService(inherited from MarshalByRefObject)       | Obtains a lifetime service object to control the lifetime policy for this instance.                                                               |
| ResetFillLoadOption(inherited from DataAdapter)                    | Resets FillLoadOption to its default state and causes Fill to honor AcceptChangesDuringFill.                                                      |
| ShouldSerializeAcceptChangesDuringFill(inherited from DataAdapter) | Determines whether the AcceptChangesDuringFill property should be persisted.                                                                      |
| ShouldSerializeFillLoadOption(inherited from DataAdapter)          | Determines whether the FillLoadOption property should be persisted.                                                                               |
| ToString(inherited from Component)                                 | Returns a String containing the name of the Component, if any. This method should not be overridden.                                              |
| Update(inherited from DbDataAdapter)                               | Overloaded. Calls the respective INSERT, UPDATE, or DELETE statements for each inserted, updated, or deleted row in the specified DataSet.        |

### Public Instance Events

|                                       |                                                                                                                               |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Disposed(inherited from Component)    | Adds an event handler to listen to the Disposed event on the component.                                                       |
| FillError(inherited from DataAdapter) | Returned when an error occurs during a fill operation.                                                                        |
| <a href="#">RowUpdated</a>            | Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.  |
| <a href="#">RowUpdating</a>           | Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires. |

### Protected Internal Instance Properties

|                                                   |                                                                         |
|---------------------------------------------------|-------------------------------------------------------------------------|
| FillCommandBehavior(inherited from DbDataAdapter) | Gets or sets the behavior of the command used to fill the data adapter. |
|---------------------------------------------------|-------------------------------------------------------------------------|

## 29.2.4.1.3.1.2.2.1.1.4. SelectCommand Property

**Syntax: Visual Basic**

```
Overloads Public Property SelectCommand As MySqlCommand
```

**Syntax: C#**

```
new public MySqlCommand SelectCommand {get; set;}
```

**See Also**

[MySqlCommandAdapter Class](#) , [MySql.Data.MySqlCommand Namespace](#)

## 29.2.4.1.3.1.2.2.1.1.5. UpdateCommand Property

**Syntax: Visual Basic**

```
Overloads Public Property UpdateCommand As MySqlCommand
```

**Syntax: C#**

```
new public MySqlCommand UpdateCommand {get; set;}
```

**See Also**

[MySqlCommandAdapter Class](#) , [MySql.Data.MySqlCommand Namespace](#)

## 29.2.4.1.3.1.2.2.1.1.6. MySqlCommandAdapter.RowUpdated Event

Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.

**Syntax: Visual Basic**

```
Public Event RowUpdated As MySqlRowUpdatedEventHandler
```

**Syntax: C#**

```
public event MySqlRowUpdatedEventHandler RowUpdated;
```

**Event Data**

The event handler receives an argument of type [MySqlRowUpdatedEventArgs](#) containing data related to this event. The following [MySqlRowUpdatedEventArgs](#) properties provide information specific to this event.

| Property                | Description                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">Command</a> | Gets or sets the MySqlCommand executed when Update is called.                                |
| Errors                  | Gets any errors generated by the .NET Framework data provider when the Command was executed. |
| RecordsAffected         | Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.     |
| Row                     | Gets the DataRow sent through an Update.                                                     |
| RowCount                | Gets the number of rows processed in a batch of updated records.                             |
| StatementType           | Gets the type of SQL statement executed.                                                     |
| Status                  | Gets the UpdateStatus of the Command property.                                               |
| TableMapping            | Gets the DataTableMapping sent through an Update.                                            |

**See Also**

[MySqlCommandAdapter Class](#) , [MySql.Data.MySqlCommand Namespace](#)

## 29.2.4.1.3.1.2.2.1.1.6.1. MySqlCommandAdapter.RowUpdatedEventHandler Delegate

Represents the method that will handle the RowUpdated event of a [MySqlCommandAdapter](#) .

**Syntax: Visual Basic**

```
Public Delegate Sub MySqlCommandAdapterRowUpdatedEventHandler(_
 ByVal sender As Object, _
 ByVal e As MySqlCommandAdapterRowUpdatedEventArgs _
)
```

**Syntax: C#**

```
public delegate void MySqlRowUpdatedEventHandler(
 object sender,
 MySqlRowUpdatedEventArgs e
);
```

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

[MySql.Data.MySqlClient Namespace](#)

**29.2.4.1.3.1.2.2.1.1.6.1.1. MySqlRowUpdatedEventArgs Class**

Provides data for the RowUpdated event. This class cannot be inherited.

For a list of all members of this type, see [MySqlRowUpdatedEventArgs Members](#).

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlRowUpdatedEventArgs_
 Inherits RowUpdatedEventArgs
```

**Syntax: C#**

```
public sealed class MySqlRowUpdatedEventArgs : RowUpdatedEventArgs
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

**Public Instance Constructors**

|                                                      |                                                                   |
|------------------------------------------------------|-------------------------------------------------------------------|
| <a href="#">MySqlRowUpdatedEventArgs Constructor</a> | Initializes a new instance of the MySqlRowUpdatedEventArgs class. |
|------------------------------------------------------|-------------------------------------------------------------------|

**Public Instance Properties**

|                                                     |                                                                                              |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">Command</a>                             | Overloaded. Gets or sets the MySqlCommand executed when Update is called.                    |
| Errors(inherited from RowUpdatedEventArgs)          | Gets any errors generated by the .NET Framework data provider when the Command was executed. |
| RecordsAffected(inherited from RowUpdatedEventArgs) | Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.     |
| Row(inherited from RowUpdatedEventArgs)             | Gets the DataRow sent through an Update.                                                     |
| RowCount(inherited from RowUpdatedEventArgs)        | Gets the number of rows processed in a batch of updated records.                             |

|                                                   |                                                  |
|---------------------------------------------------|--------------------------------------------------|
| StatementType(inherited from RowUpdatedEventArgs) | Gets the type of SQL statement executed.         |
| Status(inherited from RowUpdatedEventArgs)        | Gets the UpdateStatusof the Commandproperty.     |
| TableMapping(inherited from RowUpdatedEventArgs)  | Gets the DataTableMappingsent through an Update. |

### Public Instance Methods

|                                                |                                                                                                                                              |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| CopyToRows(inherited from RowUpdatedEventArgs) | Overloaded. Copies references to the modified rows into the provided array.                                                                  |
| Equals(inherited from Object)                  | Determines whether the specified Objectis equal to the current Object.                                                                       |
| GetHashCode(inherited from Object)             | Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table. |
| GetType(inherited from Object)                 | Gets the Typeof the current instance.                                                                                                        |
| ToString(inherited from Object)                | Returns a Stringthat represents the current Object.                                                                                          |

#### 29.2.4.1.3.1.2.2.1.1.6.1.1.1.1. MySQLRowUpdatedEventArgs Constructor

Initializes a new instance of the MySQLRowUpdatedEventArgs class.

#### Syntax: Visual Basic

```
Public Sub New(_
 ByVal row As DataRow, _
 ByVal command As IDbCommand, _
 ByVal statementType As StatementType, _
 ByVal tableMapping As DataTableMapping _
)
```

#### Syntax: C#

```
public MySQLRowUpdatedEventArgs(
 DataRow row,
 IDbCommand command,
 StatementType statementType,
 DataTableMapping tableMapping
);
```

#### Parameters

- **row**: The DataRow sent through an Update.
- **command**: The IDbCommand executed when Update is called.
- **statementType**: One of the StatementType values that specifies the type of query executed.
- **tableMapping**: The DataTableMapping sent through an Update.

#### 29.2.4.1.3.1.2.2.1.1.6.1.1.1.2. Command Property

Gets or sets the MySqlCommand executed when Update is called.

#### Syntax: Visual Basic

```
Overloads Public ReadOnly Property Command As MySqlCommand
```

#### Syntax: C#

```
new public MySqlCommand Command {get;}
```

**See Also**

[MySqlRowUpdatedEventArgs Class](#) , [MySql.Data.MySqlClient Namespace](#)

29.2.4.1.3.1.2.2.1.1.7. [MySqlDataAdapter.RowUpdating](#) Event

Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires.

**Syntax: Visual Basic**

```
Public Event RowUpdating As MySqlRowUpdatingEventHandler
```

**Syntax: C#**

```
public event MySqlRowUpdatingEventHandler RowUpdating;
```

**Event Data**

The event handler receives an argument of type [MySqlRowUpdatingEventArgs](#) containing data related to this event. The following [MySqlRowUpdatingEventArgs](#) properties provide information specific to this event.

| Property                | Description                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">Command</a> | Gets or sets the MySqlCommand to execute when performing the Update.                                |
| Errors                  | Gets any errors generated by the .NET Framework data provider when the Command executes.            |
| Row                     | Gets the DataRow that will be sent to the server as part of an insert, update, or delete operation. |
| StatementType           | Gets the type of SQL statement to execute.                                                          |
| Status                  | Gets or sets the UpdateStatus of the Command property.                                              |
| TableMapping            | Gets the DataTableMapping to send through the Update.                                               |

29.2.4.1.3.1.2.2.1.1.7.1. [MySqlRowUpdatingEventHandler](#) Delegate

Represents the method that will handle the RowUpdating event of a [MySqlDataAdapter](#) .

**Syntax: Visual Basic**

```
Public Delegate Sub MySqlRowUpdatingEventHandler(_
 ByVal sender As Object, _
 ByVal e As MySqlRowUpdatingEventArgs _
)
```

**Syntax: C#**

```
public delegate void MySqlRowUpdatingEventHandler(
 object sender,
 MySqlRowUpdatingEventArgs e
);
```

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

### 29.2.4.1.3.1.2.2.1.1.7.1.1. [MySQLRowUpdatingEventArgs](#) Class

Provides data for the RowUpdating event. This class cannot be inherited.

For a list of all members of this type, see [MySQLRowUpdatingEventArgs Members](#).

#### Syntax: Visual Basic

```
NotInheritable Public Class MySQLRowUpdatingEventArgs_
 Inherits RowUpdatingEventArgs
```

#### Syntax: C#

```
public sealed class MySQLRowUpdatingEventArgs : RowUpdatingEventArgs
```

#### Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

#### Requirements

Namespace: [MySQL.Data.MySqlCommand](#)

Assembly: MySQL.Data (in MySQL.Data.dll)

#### See Also

#### 29.2.4.1.3.1.2.2.1.1.7.1.1.1.1. MySQLRowUpdatingEventArgs Constructor

Initializes a new instance of the MySQLRowUpdatingEventArgs class.

##### Syntax: Visual Basic

```
Public Sub New(_
 ByVal row As DataRow, _
 ByVal command As IDbCommand, _
 ByVal statementType As StatementType, _
 ByVal tableMapping As DataTableMapping _
)
```

##### Syntax: C#

```
public MySQLRowUpdatingEventArgs(
 DataRow row,
 IDbCommand command,
 StatementType statementType,
 DataTableMapping tableMapping
);
```

##### Parameters

- **row**: The DataRow to update.
- **command**: The IDbCommand to execute during update.
- **statementType**: One of the StatementType values that specifies the type of query executed.
- **tableMapping**: The DataTableMapping sent through an update.

**29.2.4.1.4. MySqlConnectionException Class**

The exception that is thrown when MySQL returns an error. This class cannot be inherited.

For a list of all members of this type, see [MySqlConnectionException Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlConnectionException
 Inherits SystemException
```

**Syntax: C#**

```
public sealed class MySqlConnectionException : SystemException
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

### Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

##### Public Instance Properties

|                                          |                                                                                                             |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Data(inherited from Exception)           | Gets a collection of key/value pairs that provide additional, user-defined information about the exception. |
| HelpLink(inherited from Exception)       | Gets or sets a link to the help file associated with this exception.                                        |
| InnerException(inherited from Exception) | Gets the Exception instance that caused the current exception.                                              |
| Message(inherited from Exception)        | Gets a message that describes the current exception.                                                        |
| <a href="#">Number</a>                   | Gets a number that identifies the type of error.                                                            |
| Source(inherited from Exception)         | Gets or sets the name of the application or the object that causes the error.                               |
| StackTrace(inherited from Exception)     | Gets a string representation of the frames on the call stack at the time the current exception was thrown.  |
| TargetSite(inherited from Exception)     | Gets the method that throws the current exception.                                                          |

##### Public Instance Methods

|                                            |                                                                                                                                               |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Equals(inherited from Object)              | Determines whether the specified Object is equal to the current Object.                                                                       |
| GetBaseException(inherited from Exception) | When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.                        |
| GetHashCode(inherited from Object)         | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetObjectData(inherited from Exception)    | When overridden in a derived class, sets the SerializationInfo with information about the exception.                                          |
| GetType(inherited from Exception)          | Gets the runtime type of the current instance.                                                                                                |
| ToString(inherited from Exception)         | Creates and returns a string representation of the current exception.                                                                         |

[MySQLHelper Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.5.1.1. [MySQLHelper.ExecuteDataRow](#) Method

Executes a single SQL statement and returns the first row of the resultset. A new [MySQLConnection](#) object is created, opened, and closed during this method.

**Syntax: Visual Basic**

```
Public Shared Function ExecuteDataRow(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
 ParamArray parms As MySqlParameter() _
) As DataRow
```

**Syntax: C#**

```
public static DataRow ExecuteDataRow(
 string connectionString,
 string commandText,
 params MySqlParameter[] parms
);
```

**Parameters**

- [connectionString](#): Settings to be used for the connection
- [commandText](#): Command to execute
- [parms](#): Parameters to use for the command

**Return Value**

DataRow containing the first row of the resultset

**See Also**

[MySQLHelper Class](#) , [MySQL.Data.MySqlClient Namespace](#)

29.2.4.1.5.1.2. [ExecuteDataset](#) Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySQLConnection](#) object remains unchanged after execution of this method.

**Overload List**

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySQLConnection](#) object remains unchanged after execution of this method.

- [public static DataSet ExecuteDataset\(MySqlConnection,string\);](#)

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySQLConnection](#) object remains unchanged after execution of this method.

- [public static DataSet ExecuteDataset\(MySqlConnection,string,params MySqlParameter\[\]\);](#)

Executes a single SQL statement and returns the resultset in a DataSet. A new [MySQLConnection](#) object is created, opened, and closed during this method.

- [public static DataSet ExecuteDataset\(string,string\);](#)

Executes a single SQL statement and returns the resultset in a DataSet. A new [MySQLConnection](#) object is created, opened, and closed during this method.

- `public static DataSet ExecuteDataset(string,string,params MySqlParameter[]);`

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

29.2.4.1.5.1.2.1. [MySqlHelper.ExecuteDataset](#) Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteDataset(_
 ByVal connection As MySqlConnection, _
 ByVal commandText As String _
) As DataSet
```

**Syntax: C#**

```
public static DataSet ExecuteDataset(
 MySqlConnectionconnection,
 stringcommandText
);
```

**Parameters**

- `connection`: [MySqlConnection](#) object to use
- `commandText`: Command to execute

**Return Value**

DataSetcontaining the resultset

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteDataset Overload List](#)

29.2.4.1.5.1.2.2. [MySqlHelper.ExecuteDataset](#) Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteDataset(_
 ByVal connection As MySqlConnection, _
 ByVal commandText As String, _
 ParamArray commandParameters As MySqlParameter() _
) As DataSet
```

**Syntax: C#**

```
public static DataSet ExecuteDataset(
 MySqlConnectionconnection,
 stringcommandText,
 params MySqlParameter[]commandParameters
);
```

**Parameters**

- `connection`: [MySqlConnection](#) object to use
- `commandText`: Command to execute
- `commandParameters`: Parameters to use for the command

**Return Value**

DataSetcontaining the resultset

**See Also**

[MySQLHelper Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLHelper.ExecuteDataset Overload List](#)

#### 29.2.4.1.5.1.2.3. [MySQLHelper.ExecuteDataset](#) Method

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteDataset(_
 ByVal connectionString As String, _
 ByVal commandText As String _
) As DataSet
```

**Syntax: C#**

```
public static DataSet ExecuteDataset(
 stringconnectionString,
 stringcommandText
);
```

**Parameters**

- [connectionString](#): Settings to be used for the connection
- [commandText](#): Command to execute

**Return Value**

DataSetcontaining the resultset

**See Also**

[MySQLHelper Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLHelper.ExecuteDataset Overload List](#)

#### 29.2.4.1.5.1.2.4. [MySQLHelper.ExecuteDataset](#) Method

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteDataset(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
 ParamArray commandParameters As MySqlParameter() _
) As DataSet
```

**Syntax: C#**

```
public static DataSet ExecuteDataset(
 stringconnectionString,
 stringcommandText,
 params MySqlParameter[]commandParameters
);
```

**Parameters**

- [connectionString](#): Settings to be used for the connection
- [commandText](#): Command to execute
- [commandParameters](#): Parameters to use for the command

**Return Value**

DataSet containing the resultset

#### See Also

### 29.2.4.1.5.1.3. ExecuteNonQuery Method

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

#### Overload List

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

- `public static int ExecuteNonQuery(MySqlConnection, string, params MySqlParameter[]);`

Executes a single command against a MySQL database. A new [MySqlConnection](#) is created using the [ConnectionString](#) given.

- `public static int ExecuteNonQuery(string, string, params MySqlParameter[]);`

#### See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 29.2.4.1.5.1.3.1. MySqlHelper.ExecuteNonQuery Method

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

#### Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery(_
 ByVal connection As MySqlConnection, _
 ByVal commandText As String, _
 ParamArray commandParameters As MySqlParameter() _
) As Integer
```

#### Syntax: C#

```
public static int ExecuteNonQuery(
 MySqlConnection connection,
 string commandText,
 params MySqlParameter[] commandParameters
);
```

#### Parameters

- `connection`: [MySqlConnection](#) object to use
- `commandText`: SQL statement to be executed
- `commandParameters`: Array of [MySqlParameter](#) objects to use with the command.

#### Return Value

#### See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteNonQuery Overload List](#)

### 29.2.4.1.5.1.3.2. MySqlHelper.ExecuteNonQuery Method

Executes a single command against a MySQL database. A new [MySqlConnection](#) is created using the [ConnectionString](#) given.

#### Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
 ParamArray parms As MySqlParameter() _
) As Integer
```

**Syntax: C#**

```
public static int ExecuteNonQuery(
 string connectionString,
 string commandText,
 params MySqlParameter[] parms
);
```

**Parameters**

- `connectionString`: [ConnectionString](#) to use
- `commandText`: SQL statement to be executed
- `parms`: Array of [MySqlParameter](#) objects to use with the command.

**Return Value****See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteNonQuery Overload List](#)

**29.2.4.1.5.1.4. ExecuteReader Method**

Executes a single command against a MySQL database.

**Overload List**

Executes a single command against a MySQL database.

- [public static MySqlDataReader ExecuteReader\(string,string\);](#)

Executes a single command against a MySQL database.

- [public static MySqlDataReader ExecuteReader\(string,string,params MySqlParameter\[\]\);](#)

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

**29.2.4.1.5.1.4.1. MySqlHelper.ExecuteReader Method**

Executes a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteReader(_
 ByVal connectionString As String, _
 ByVal commandText As String _
) As MySqlDataReader
```

**Syntax: C#**

```
public static MySqlDataReader ExecuteReader(
 string connectionString,
 string commandText
);
```

**Parameters**

- `connectionString`: Settings to use for this command

- `commandText`: Command text to use

**Return Value**

[MySqlDataReader](#) object ready to read the results of the command

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteReader Overload List](#)

#### 29.2.4.1.5.1.4.2. [MySqlHelper.ExecuteReader](#) Method

Executes a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteReader(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
 ParamArray commandParameters As MySqlParameter() _
) As MySqlDataReader
```

**Syntax: C#**

```
public static MySqlDataReader ExecuteReader(
 string connectionString,
 string commandText,
 params MySqlParameter[] commandParameters
);
```

**Parameters**

- `connectionString`: Settings to use for this command
- `commandText`: Command text to use
- `commandParameters`: Array of [MySqlParameter](#) objects to use with the command

**Return Value**

[MySqlDataReader](#) object ready to read the results of the command

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteReader Overload List](#)

#### 29.2.4.1.5.1.5. ExecuteScalar Method

Execute a single command against a MySQL database.

**Overload List**

Execute a single command against a MySQL database.

- `public static object ExecuteScalar(MySqlConnection,string);`

Execute a single command against a MySQL database.

- `public static object ExecuteScalar(MySqlConnection,string,params MySqlParameter[]);`

Execute a single command against a MySQL database.

- `public static object ExecuteScalar(string,string);`

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(string,string,params MySqlParameter\[\]\);](#)

#### See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.5.1.5.1. [MySqlHelper.ExecuteScalar](#) Method

Execute a single command against a MySQL database.

##### Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar(_
 ByVal connection As MySqlConnection, _
 ByVal commandText As String _
) As Object
```

##### Syntax: C#

```
public static object ExecuteScalar(
 MySqlConnectionconnection,
 stringcommandText
);
```

##### Parameters

- [connection](#): [MySqlConnection](#) object to use
- [commandText](#): Command text to use for the command

##### Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

#### See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteScalar Overload List](#)

#### 29.2.4.1.5.1.5.2. [MySqlHelper.ExecuteScalar](#) Method

Execute a single command against a MySQL database.

##### Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar(_
 ByVal connection As MySqlConnection, _
 ByVal commandText As String, _
 ParamArray commandParameters As MySqlParameter() _
) As Object
```

##### Syntax: C#

```
public static object ExecuteScalar(
 MySqlConnectionconnection,
 stringcommandText,
 params MySqlParameter[]commandParameters
);
```

##### Parameters

- [connection](#): [MySqlConnection](#) object to use
- [commandText](#): Command text to use for the command
- [commandParameters](#): Parameters to use for the command

**Return Value**

The first column of the first row in the result set, or a null reference if the result set is empty.

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteScalar Overload List](#)

**29.2.4.1.5.1.5.3. [MySqlHelper.ExecuteScalar](#) Method**

Execute a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteScalar(_
 ByVal connectionString As String, _
 ByVal commandText As String _
) As Object
```

**Syntax: C#**

```
public static object ExecuteScalar(
 string connectionString,
 string commandText
);
```

**Parameters**

- `connectionString`: Settings to use for the update
- `commandText`: Command text to use for the update

**Return Value**

The first column of the first row in the result set, or a null reference if the result set is empty.

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteScalar Overload List](#)

**29.2.4.1.5.1.5.4. [MySqlHelper.ExecuteScalar](#) Method**

Execute a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteScalar(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
 ParamArray commandParameters As MySqlParameter() _
) As Object
```

**Syntax: C#**

```
public static object ExecuteScalar(
 string connectionString,
 string commandText,
 params MySqlParameter[] commandParameters
);
```

**Parameters**

- `connectionString`: Settings to use for the command
- `commandText`: Command text to use for the command
- `commandParameters`: Parameters to use for the command

**Return Value**

The first column of the first row in the result set, or a null reference if the result set is empty.

#### See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteScalar Overload List](#)

#### 29.2.4.1.5.1.6. `MySqlHelper.UpdateDataSet` Method

Updates the given table with data from the given DataSet

##### Syntax: Visual Basic

```
Public Shared Sub UpdateDataSet(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
 ByVal ds As DataSet, _
 ByVal tablename As String _
)
```

##### Syntax: C#

```
public static void UpdateDataSet(
 stringconnectionString,
 stringcommandText,
 DataSetds,
 stringtablename
);
```

#### Parameters

- `connectionString`: Settings to use for the update
- `commandText`: Command text to use for the update
- `ds`: DataSetcontaining the new data to use in the update
- `tablename`: Tablename in the data set to update

#### See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 29.2.4.1.6. `MySqlErrorCode` Enumeration

##### Syntax: Visual Basic

```
Public Enum MySqlErrorCode
```

##### Syntax: C#

```
public enum MySqlErrorCode
```

#### Members

| Member Name        | Description |
|--------------------|-------------|
| PacketTooLarge     |             |
| PasswordNotAllowed |             |
| DuplicateKeyEntry  |             |
| HostNotPrivileged  |             |
| PasswordNoMatch    |             |
| AnonymousUser      |             |
| DuplicateKey       |             |
| KeyNotFound        |             |
| DuplicateKeyName   |             |

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

|------------------------------------------------------|------|
| <a href="#">MySqlConversionException Constructor</a> | Ctor |
|------------------------------------------------------|------|

**Public Instance Properties**

|                                          |                                                                                                             |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Data(inherited from Exception)           | Gets a collection of key/value pairs that provide additional, user-defined information about the exception. |
| HelpLink(inherited from Exception)       | Gets or sets a link to the help file associated with this exception.                                        |
| InnerException(inherited from Exception) | Gets the Exceptioninstance that caused the current exception.                                               |
| Message(inherited from Exception)        | Gets a message that describes the current exception.                                                        |
| Source(inherited from Exception)         | Gets or sets the name of the application or the object that causes the error.                               |
| StackTrace(inherited from Exception)     | Gets a string representation of the frames on the call stack at the time the current exception was thrown.  |
| TargetSite(inherited from Exception)     | Gets the method that throws the current exception.                                                          |

**Public Instance Methods**

|                                            |                                                                                                                                              |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Equals(inherited from Object)              | Determines whether the specified Objectis equal to the current Object.                                                                       |
| GetBaseException(inherited from Exception) | When overridden in a derived class, returns the Exceptionthat is the root cause of one or more subsequent exceptions.                        |
| GetHashCode(inherited from Object)         | Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table. |
| GetObjectData(inherited from Exception)    | When overridden in a derived class, sets the SerializationIn-<br>fowith information about the exception.                                     |
| GetType(inherited from Exception)          | Gets the runtime type of the current instance.                                                                                               |
| ToString(inherited from Exception)         | Creates and returns a string representation of the current excep-<br>tion.                                                                   |

**Protected Instance Properties**

|                                   |                                                                                              |
|-----------------------------------|----------------------------------------------------------------------------------------------|
| HResult(inherited from Exception) | Gets or sets HRESULT, a coded numerical value that is as-<br>signed to a specific exception. |
|-----------------------------------|----------------------------------------------------------------------------------------------|

**Protected Instance Methods**

|                                        |                                                                                                                                              |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Finalize(inherited from Object)        | Allows an Objectto attempt to free resources and perform other<br>cleanup operations before the Objectis reclaimed by garbage<br>collection. |
| MemberwiseClone(inherited from Object) | Creates a shallow copy of the current Object.                                                                                                |

#### Public Instance Properties

|                                                           |                                                                                 |
|-----------------------------------------------------------|---------------------------------------------------------------------------------|
| <a href="#">Day</a>                                       | Returns the day portion of this datetime                                        |
| <a href="#">Hour</a>                                      | Returns the hour portion of this datetime                                       |
| <a href="#">IsNull</a> (inherited from MySQLValue)        |                                                                                 |
| <a href="#">IsValidDateTime</a>                           | Indicates if this object contains a value that can be represented as a DateTime |
| <a href="#">Minute</a>                                    | Returns the minute portion of this datetime                                     |
| <a href="#">Month</a>                                     | Returns the month portion of this datetime                                      |
| <a href="#">Second</a>                                    | Returns the second portion of this datetime                                     |
| <a href="#">ValueAsObject</a> (inherited from MySQLValue) | Returns the value of this field as an object                                    |
| <a href="#">Year</a>                                      | Returns the year portion of this datetime                                       |

#### Public Instance Methods

|                                                     |                                                                                                                                               |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Equals</a> (inherited from Object)      | Determines whether the specified Object is equal to the current Object.                                                                       |
| <a href="#">GetDateTime</a>                         | Returns this value as a DateTime                                                                                                              |
| <a href="#">GetHashCode</a> (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| <a href="#">GetType</a> (inherited from Object)     | Gets the Type of the current instance.                                                                                                        |
| <a href="#">ToString</a>                            | Returns a MySQL specific string representation of this value                                                                                  |

**Protected Instance Fields**

|                                                                            |                                           |
|----------------------------------------------------------------------------|-------------------------------------------|
| <a href="#">classType</a> (inherited from <a href="#">MySqlValue</a> )     | The system type represented by this value |
| <a href="#">dbType</a> (inherited from <a href="#">MySqlValue</a> )        | The generic dbtype of this value          |
| <a href="#">isNull</a> (inherited from <a href="#">MySqlValue</a> )        | Is this value null                        |
| <a href="#">mysqlDbType</a> (inherited from <a href="#">MySqlValue</a> )   | The specific MySQL db type                |
| <a href="#">mysqlTypeName</a> (inherited from <a href="#">MySqlValue</a> ) | The MySQL specific typename of this value |
| <a href="#">objectValue</a> (inherited from <a href="#">MySqlValue</a> )   |                                           |

**Protected Instance Methods**

|                                                                          |                                                                                                                                          |
|--------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Finalize</a> (inherited from <a href="#">Object</a> )        | Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection. |
| <a href="#">MemberwiseClone</a> (inherited from <a href="#">Object</a> ) | Creates a shallow copy of the current Object.                                                                                            |

29.2.4.2.3.1.4.1.1.2. [MySQLValue](#) Constructor

Initializes a new instance of the [MySQLValue](#) class.

**Syntax: Visual Basic**

```
Public Sub New()
```

**Syntax: C#**

```
public MySQLValue();
```

**See Also**

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

## 29.2.4.2.3.1.4.1.1.3. ValueAsObject Property

Returns the value of this field as an object

**Syntax: Visual Basic**

```
Public ReadOnly Property ValueAsObject As Object
```

**Syntax: C#**

```
public object ValueAsObject {get;}
```

**See Also**

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

## 29.2.4.2.3.1.4.1.1.4. MySqlValue.ToString Method

Returns a string representation of this value

**Syntax: Visual Basic**

```
Overrides Public Function ToString() As String
```

**Syntax: C#**

```
public override string ToString();
```

**See Also**

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

## 29.2.4.2.3.1.4.1.1.5. MySqlValue.classType Field

The system type represented by this value

**Syntax: Visual Basic**

```
Protected classType As Type
```

**Syntax: C#**

```
protected Type classType;
```

**See Also**

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

## 29.2.4.2.3.1.4.1.1.6. MySqlValue.dbType Field

The generic dbtype of this value

**Syntax: Visual Basic**

```
Protected dbType As DbType
```

**Syntax: C#**

```
protected DbType dbType;
```

**See Also**

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

#### 29.2.4.2.3.1.4.1.1.7. [MySqlValue.mysqlDbType](#) Field

The specific MySQL db type

**Syntax: Visual Basic**

```
Protected mysqlDbType As MySqlDbType
```

**Syntax: C#**

```
protected MySqlDbType mysqlDbType;
```

**See Also**

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

#### 29.2.4.2.3.1.4.1.1.8. [MySqlValue.mysqlTypeName](#) Field

The MySQL specific typename of this value

**Syntax: Visual Basic**

```
Protected mysqlTypeName As String
```

**Syntax: C#**

```
protected string mysqlTypeName;
```

**See Also**

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

#### 29.2.4.2.3.1.4.1.1.9. [MySqlValue.objectValue](#) Field

**Syntax: Visual Basic**

```
Protected objectValue As Object
```

**Syntax: C#**

```
protected object objectValue;
```

**See Also**

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

#### 29.2.4.2.3.1.5. IsValidDateTime Property

Indicates if this object contains a value that can be represented as a DateTime

**Syntax: Visual Basic**

```
Public ReadOnly Property IsValidDateTime As Boolean
```

**Syntax: C#**

```
public bool IsValidDateTime {get;}
```

**See Also**

[MySqlDateTime Class](#) , [MySql.Data.Types Namespace](#)

#### 29.2.4.2.3.1.6. Minute Property

Returns the minute portion of this datetime

**Syntax: Visual Basic**

---

```
Public Property Minute As Integer
```

**Syntax: C#**

```
public int Minute {get; set;}
```

**See Also**

[MySqlDateTime Class](#) , [MySql.Data.Types Namespace](#)

#### 29.2.4.2.3.1.7. Month Property

Returns the month portion of this datetime

**Syntax: Visual Basic**

```
Public Property Month As Integer
```

**Syntax: C#**

```
public int Month {get; set;}
```

**See Also**

[MySqlDateTime Class](#) , [MySql.Data.Types Namespace](#)

#### 29.2.4.2.3.1.8. Second Property

Returns the second portion of this datetime

**Syntax: Visual Basic**

```
Public Property Second As Integer
```

**Syntax: C#**

```
public int Second {get; set;}
```

**See Also**

[MySqlDateTime Class](#) , [MySql.Data.Types Namespace](#)

#### 29.2.4.2.3.1.9. Year Property

Returns the year portion of this datetime

**Syntax: Visual Basic**

```
Public Property Year As Integer
```

**Syntax: C#**

```
public int Year {get; set;}
```

**See Also**

[MySqlDateTime Class](#) , [MySql.Data.Types Namespace](#)

#### 29.2.4.2.3.1.10. [MySqlDateTime.GetDateTime](#) Method

Returns this value as a DateTime

**Syntax: Visual Basic**

```
Public Function GetDateTime() As Date
```

**Syntax: C#**

```
public DateTime GetDateTime();
```

**See Also**

[MySqlDateTime Class](#) , [MySql.Data.Types Namespace](#)

**29.2.4.2.3.1.11. [MySqlDateTime.ToString](#) Method**

Returns a MySQL specific string representation of this value

**Syntax: Visual Basic**

```
Overrides Public Function ToString() As String
```

**Syntax: C#**

```
public override string ToString();
```

**See Also**

[MySqlDateTime Class](#) , [MySql.Data.Types Namespace](#)

**29.2.5. Connector/NET Notes and Tips**

In this section we will cover some of the more common use cases for Connector/NET, including BLOB handling, date handling, and using Connector/NET with common tools such as Crystal Reports.

**29.2.5.1. Connecting to MySQL Using Connector/NET****29.2.5.1.1. Introduction**

All interaction between a .NET application and the MySQL server is routed through a [MySqlConnection](#) object. Before your application can interact with the server, a [MySqlConnection](#) object must be instantiated, configured, and opened.

Even when using the [MySqlHelper](#) class, a [MySqlConnection](#) object is created by the helper class.

In this section, we will describe how to connect to MySQL using the [MySqlConnection](#) object.

**29.2.5.1.2. Creating a Connection String**

The [MySqlConnection](#) object is configured using a connection string. A connection string contains several key/value pairs, separated by semicolons. Each key/value pair is joined with an equals sign.

The following is a sample connection string:

```
Server=127.0.0.1;Uid=root;Pwd=12345;Database=test;
```

In this example, the [MySqlConnection](#) object is configured to connect to a MySQL server at `127.0.0.1`, with a username of `root` and a password of `12345`. The default database for all statements will be the `test` database.

The following options are typically used (a full list of options is available in the API documentation for [Section 29.2.3.3.3](#), “[ConnectionString](#)”):

- **Server**: The name or network address of the instance of MySQL to which to connect. The default is `localhost`. Aliases include `host`, `Data Source`, `DataSource`, `Address`, `Addr` and `Network Address`.
- **Uid**: The MySQL user account to use when connecting. Aliases include `User Id`, `Username` and `User name`.
- **Pwd**: The password for the MySQL account being used. Alias `Password` can also be used.
- **Database**: The default database that all statements are applied to. Default is `mysql`. Alias `Initial Catalog` can also be used.
- **Port**: The port MySQL is using to listen for connections. Default is `3306`. Specify `-1` for this value to use a named-pipe connection.

### 29.2.5.1.3. Opening a Connection

Once you have created a connection string it can be used to open a connection to the MySQL server.

The following code is used to create a `MySqlConnection` object, assign the connection string, and open the connection.

#### Visual Basic Example

```
Dim conn As New MySql.Data.MySqlClient.MySqlConnection
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test;"

Try
 conn.ConnectionString = myConnectionString
 conn.Open()

Catch ex As MySql.Data.MySqlClient.MySqlException
 MessageBox.Show(ex.Message)
End Try
```

#### C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 conn = new MySql.Data.MySqlClient.MySqlConnection();
 conn.ConnectionString = myConnectionString;
 conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show(ex.Message);
}
```

You can also pass the connection string to the constructor of the `MySqlConnection` class:

#### Visual Basic Example

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test;"

Try
 Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
 conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
 MessageBox.Show(ex.Message)
End Try
```

#### C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
 conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show(ex.Message);
}
```

Once the connection is open it can be used by the other Connector/NET classes to communicate with the MySQL server.

### 29.2.5.1.4. Handling Connection Errors

Because connecting to an external server is unpredictable, it is important to add error handling to your .NET application. When there is an error connecting, the `MySqlConnection` class will return a `MySqlException` object. This object has two properties that are of interest when handling errors:

- **Message:** A message that describes the current exception.
- **Number:** The MySQL error number.

When handling errors, you can your application's response based on the error number. The two most common error numbers when connecting are as follows:

- **0:** Cannot connect to server.
- **1045:** Invalid username and/or password.

The following code shows how to adapt the application's response based on the actual error:

#### Visual Basic Example

```
Dim myConnectionString as String
myConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test;"

Try
 Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
 conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
 Select Case ex.Number
 Case 0
 MessageBox.Show("Cannot connect to server. Contact administrator")
 Case 1045
 MessageBox.Show("Invalid username/password, please try again")
 End Select
End Try
```

#### C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
 conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 switch (ex.Number)
 {
 case 0:
 MessageBox.Show("Cannot connect to server. Contact administrator");
 case 1045:
 MessageBox.Show("Invalid username/password, please try again");
 }
}
```

#### Important

Note that if you are using multilanguage databases you must specify the character set in the connection string. If you do not specify the character set, the connection defaults to the `latin1` charset. You can specify the character set as part of the connection string, for example:

```
MySqlConnection myConnection = new MySqlConnection("server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;Charset=latin1;");
```

## 29.2.5.2. Using the Connector/NET with Prepared Statements

### 29.2.5.2.1. Introduction

As of MySQL 4.1, it is possible to use prepared statements with Connector/NET. Use of prepared statements can provide significant performance improvements on queries that are executed more than once.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

### 29.2.5.2.2. Preparing Statements in Connector/NET

To prepare a statement, create a command object and set the `.CommandText` property to your query.

After entering your statement, call the `.Prepare` method of the `MySQLCommand` object. After the statement is prepared, add parameters for each of the dynamic elements in the query.

After you enter your query and enter parameters, execute the statement using the `.ExecuteNonQuery()`, `.ExecuteScalar()`, or `.ExecuteReader` methods.

For subsequent executions, you need only modify the values of the parameters and call the execute method again, there is no need to set the `.CommandText` property or redefine the parameters.

#### Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = strConnection

Try
 conn.Open()
 cmd.Connection = conn

 cmd.CommandText = "INSERT INTO myTable VALUES(NULL, ?number, ?text)"
 cmd.Prepare()

 cmd.Parameters.Add("?number", 1)
 cmd.Parameters.Add("?text", "One")

 For i = 1 To 1000
 cmd.Parameters["?number"].Value = i
 cmd.Parameters["?text"].Value = "A string value"

 cmd.ExecuteNonQuery()
 Next
Catch ex As MySqlException
 MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

#### C# Example

```
MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = strConnection;

try
{
 conn.Open();
 cmd.Connection = conn;

 cmd.CommandText = "INSERT INTO myTable VALUES(NULL, ?number, ?text)";
 cmd.Prepare();

 cmd.Parameters.Add("?number", 1);
 cmd.Parameters.Add("?text", "One");

 for (int i=1; i <= 1000; i++)
 {
 cmd.Parameters["?number"].Value = i;
 cmd.Parameters["?text"].Value = "A string value";

 cmd.ExecuteNonQuery();
 }
}
catch (MySQL.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
 "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

}

### 29.2.5.3. Accessing Stored Procedures with Connector/NET

#### 29.2.5.3.1. Introduction

With the release of MySQL version 5 the MySQL server now supports stored procedures with the SQL 2003 stored procedure syntax.

A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored procedure instead.

Stored procedures can be particularly useful in situations such as the following:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures for all common operations. This provides a consistent and secure environment, and procedures can ensure that each operation is properly logged. In such a setup, applications and users would not get any access to the database tables directly, but can only execute specific stored procedures.

Connector/NET supports the calling of stored procedures through the `MySQLCommand` object. Data can be passed in and out of a MySQL stored procedure through use of the `MySQLCommand.Parameters` collection.

#### Note

When you call a stored procedure, the command object makes an additional `SELECT` call to determine the parameters of the stored procedure. You must ensure that the user calling the procedure has the `SELECT` privilege on the `mysql.proc` table to enable them to verify the parameters. Failure to do this will result in an error when calling the procedure.

This section will not provide in-depth information on creating Stored Procedures. For such information, please refer to <http://dev.mysql.com/doc/mysql/en/stored-procedures.html>.

A sample application demonstrating how to use stored procedures with Connector/NET can be found in the `Samples` directory of your Connector/NET installation.

#### 29.2.5.3.2. Creating Stored Procedures from Connector/NET

Stored procedures in MySQL can be created using a variety of tools. First, stored procedures can be created using the `mysql` command-line client. Second, stored procedures can be created using the `MySQL Query Browser` GUI client. Finally, stored procedures can be created using the `.ExecuteNonQuery` method of the `MySQLCommand` object:

##### Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = "server=127.0.0.1;" & _
 & "uid=root;" & _
 & "pwd=12345;" & _
 & "database=test"

Try
 conn.Open()
 cmd.Connection = conn

 cmd.CommandText = "CREATE PROCEDURE add_emp(" & _
 & "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empno INT) " & _
 & "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " & _
 & "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END"

 cmd.ExecuteNonQuery()
Catch ex As MySqlException
 MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

##### C# Example

```
MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();
```

```

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 conn.Open();
 cmd.Connection = conn;

 cmd.CommandText = "CREATE PROCEDURE add_emp(" +
 "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empno INT) " +
 "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " +
 "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END";

 cmd.ExecuteNonQuery();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
 "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

It should be noted that, unlike the command-line and GUI clients, you are not required to specify a special delimiter when creating stored procedures in Connector/NET.

### 29.2.5.3.3. Calling a Stored Procedure from Connector/NET

To call a stored procedure using Connector/NET, create a `MySqlCommand` object and pass the stored procedure name as the `.CommandText` property. Set the `.CommandType` property to `CommandType.StoredProcedure`.

After the stored procedure is named, create one `MySqlCommand` parameter for every parameter in the stored procedure. `IN` parameters are defined with the parameter name and the object containing the value, `OUT` parameters are defined with the parameter name and the datatype that is expected to be returned. All parameters need the parameter direction defined.

After defining parameters, call the stored procedure by using the `MySqlCommand.ExecuteNonQuery()` method:

#### Visual Basic Example

```

Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test"

Try
 conn.Open()
 cmd.Connection = conn

 cmd.CommandText = "add_emp"
 cmd.CommandType = CommandType.StoredProcedure

 cmd.Parameters.Add("?lname", 'Jones')
 cmd.Parameters["?lname"].Direction = ParameterDirection.Input

 cmd.Parameters.Add("?fname", 'Tom')
 cmd.Parameters["?fname"].Direction = ParameterDirection.Input

 cmd.Parameters.Add("?bday", #12/13/1977 2:17:36 PM#)
 cmd.Parameters["?bday"].Direction = ParameterDirection.Input

 cmd.Parameters.Add("?empno", MySqlDbType.Int32)
 cmd.Parameters["?empno"].Direction = ParameterDirection.Output

 cmd.ExecuteNonQuery()

 MessageBox.Show(cmd.Parameters["?empno"].Value)
Catch ex As MySqlException
 MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

#### C# Example

```

MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 conn.Open();
 cmd.Connection = conn;

```

```

cmd.CommandText = "add_emp";
cmd.CommandType = CommandType.StoredProcedure;

cmd.Parameters.Add("?lname", "Jones");
cmd.Parameters["?lname"].Direction = ParameterDirection.Input;

cmd.Parameters.Add("?fname", "Tom");
cmd.Parameters["?fname"].Direction = ParameterDirection.Input;

cmd.Parameters.Add("?bday", DateTime.Parse("12/13/1977 2:17:36 PM"));
cmd.Parameters["?bday"].Direction = ParameterDirection.Input;

cmd.Parameters.Add("?empno", MySqlDbType.Int32);
cmd.Parameters["?empno"].Direction = ParameterDirection.Output;

cmd.ExecuteNonQuery();

MessageBox.Show(cmd.Parameters["?empno"].Value);
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
 "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

Once the stored procedure is called, the values of output parameters can be retrieved by using the `.Value` property of the `MySqlConnection.Parameters` collection.

## 29.2.5.4. Handling BLOB Data With Connector/NET

### 29.2.5.4.1. Introduction

One common use for MySQL is the storage of binary data in **BLOB** columns. MySQL supports four different BLOB datatypes: `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`.

Data stored in a BLOB column can be accessed using Connector/NET and manipulated using client-side code. There are no special requirements for using Connector/NET with BLOB data.

Simple code examples will be presented within this section, and a full sample application can be found in the `Samples` directory of the Connector/NET installation.

### 29.2.5.4.2. Preparing the MySQL Server

The first step in using MySQL with BLOB data is to configure the server. Let's start by creating a table to be accessed. In my file tables, I usually have four columns: an `AUTO_INCREMENT` column of appropriate size (`UNSIGNED SMALLINT`) to serve as a primary key to identify the file, a `VARCHAR` column that stores the filename, an `UNSIGNED MEDIUMINT` column that stores the size of the file, and a `MEDIUMBLOB` column that stores the file itself. For this example, I will use the following table definition:

```

CREATE TABLE file(
file_id SMALLINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
file_name VARCHAR(64) NOT NULL,
file_size MEDIUMINT UNSIGNED NOT NULL,
file MEDIUMBLOB NOT NULL);

```

After creating a table, you may need to modify the `max_allowed_packet` system variable. This variable determines how large of a packet (i.e. a single row) can be sent to the MySQL server. By default, the server will only accept a maximum size of 1 meg from our client application. If you do not intend to exceed 1 meg, this should be fine. If you do intend to exceed 1 meg in your file transfers, this number has to be increased.

The `max_allowed_packet` option can be modified using MySQL Administrator's Startup Variables screen. Adjust the Maximum allowed option in the Memory section of the Networking tab to an appropriate setting. After adjusting the value, click the `APPLY CHANGES` button and restart the server using the `Service Control` screen of MySQL Administrator. You can also adjust this value directly in the `my.cnf` file (add a line that reads `max_allowed_packet=xxM`), or use the `SET max_allowed_packet=xxM`; syntax from within MySQL.

Try to be conservative when setting `max_allowed_packet`, as transfers of BLOB data can take some time to complete. Try to set a value that will be adequate for your intended use and increase the value if necessary.

### 29.2.5.4.3. Writing a File to the Database

To write a file to a database we need to convert the file to a byte array, then use the byte array as a parameter to an `INSERT` query.

The following code opens a file using a `FileStream` object, reads it into a byte array, and inserts it into the `file` table:

## Visual Basic Example

```

Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

Dim SQL As String

Dim FileSize As UInt32
Dim rawData() As Byte
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test"

Try
 fs = New FileStream("c:\image.png", FileMode.Open, FileAccess.Read)
 FileSize = fs.Length

 rawData = New Byte(FileSize) {}
 fs.Read(rawData, 0, FileSize)
 fs.Close()

 conn.Open()

 SQL = "INSERT INTO file VALUES(NULL, ?FileName, ?FileSize, ?File)"

 cmd.Connection = conn
 cmd.CommandText = SQL
 cmd.Parameters.Add("?FileName", strFileName)
 cmd.Parameters.Add("?FileSize", FileSize)
 cmd.Parameters.Add("?File", rawData)

 cmd.ExecuteNonQuery()

 MessageBox.Show("File Inserted into database successfully!", _
 "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

 conn.Close()
Catch ex As Exception
 MessageBox.Show("There was an error: " & ex.Message, "Error", _
 MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

## C# Example

```

MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 fs = new FileStream(@"c:\image.png", FileMode.Open, FileAccess.Read);
 FileSize = fs.Length;

 rawData = new byte[FileSize];
 fs.Read(rawData, 0, FileSize);
 fs.Close();

 conn.Open();

 SQL = "INSERT INTO file VALUES(NULL, ?FileName, ?FileSize, ?File)";

 cmd.Connection = conn;
 cmd.CommandText = SQL;
 cmd.Parameters.Add("?FileName", strFileName);
 cmd.Parameters.Add("?FileSize", FileSize);
 cmd.Parameters.Add("?File", rawData);

 cmd.ExecuteNonQuery();

 MessageBox.Show("File Inserted into database successfully!",
 "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

 conn.Close();
}
catch (MySQL.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
 "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

The `Read` method of the `FileStream` object is used to load the file into a byte array which is sized according to the `Length` property of the `FileStream` object.

After assigning the byte array as a parameter of the `MySQLCommand` object, the `ExecuteNonQuery` method is called and the BLOB is inserted into the `file` table.

#### 29.2.5.4.4. Reading a BLOB from the Database to a File on Disk

Once a file is loaded into the `file` table, we can use the `MySQLDataReader` class to retrieve it.

The following code retrieves a row from the `file` table, then loads the data into a `FileStream` object to be written to disk:

##### Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myData As MySQLDataReader
Dim SQL As String
Dim rawData() As Byte
Dim FileSize As UInt32
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test"

SQL = "SELECT file_name, file_size, file FROM file"

Try
 conn.Open()

 cmd.Connection = conn
 cmd.CommandText = SQL

 myData = cmd.ExecuteReader

 If Not myData.HasRows Then Throw New Exception("There are no BLOBs to save")

 myData.Read()

 FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"))
 rawData = New Byte(FileSize) {}

 myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize)

 fs = New FileStream("C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write)
 fs.Write(rawData, 0, FileSize)
 fs.Close()

 MessageBox.Show("File successfully written to disk!", "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

 myData.Close()
 conn.Close()
Catch ex As Exception
 MessageBox.Show("There was an error: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

##### C# Example

```
MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;
MySQL.Data.MySqlClient.MySQLDataReader myData;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

SQL = "SELECT file_name, file_size, file FROM file";

try
{
 conn.Open();

 cmd.Connection = conn;
 cmd.CommandText = SQL;

 myData = cmd.ExecuteReader();

 if (! myData.HasRows)
 throw new Exception("There are no BLOBs to save");
```

```

myData.Read();
FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"));
rawData = new byte[FileSize];

myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize);

fs = new FileStream(@"C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write);
fs.Write(rawData, 0, FileSize);
fs.Close();

MessageBox.Show("File successfully written to disk!",
 "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

myData.Close();
conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
 "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

After connecting, the contents of the `file` table are loaded into a `MySqlDataReader` object. The `GetBytes` method of the `MySqlDataReader` is used to load the BLOB into a byte array, which is then written to disk using a `FileStream` object.

The `GetOrdinal` method of the `MySqlDataReader` can be used to determine the integer index of a named column. Use of the `GetOrdinal` method prevents errors if the column order of the `SELECT` query is changed.

## 29.2.5.5. Using Connector/NET with Crystal Reports

### 29.2.5.5.1. Introduction

Crystal Reports is a common tool used by Windows application developers to perform reporting and document generation. In this section we will show how to use Crystal Reports XI with MySQL and Connector/NET.

### 29.2.5.5.2. Creating a Data Source

When creating a report in Crystal Reports there are two options for accessing the MySQL data while designing your report.

The first option is to use Connector/ODBC as an ADO data source when designing your report. You will be able to browse your database and choose tables and fields using drag and drop to build your report. The disadvantage of this approach is that additional work must be performed within your application to produce a data set that matches the one expected by your report.

The second option is to create a data set in VB.NET and save it as XML. This XML file can then be used to design a report. This works quite well when displaying the report in your application, but is less versatile at design time because you must choose all relevant columns when creating the data set. If you forget a column you must re-create the data set before the column can be added to the report.

The following code can be used to create a data set from a query and write it to disk:

#### Visual Basic Example

```

Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=world"

Try
 conn.Open()
 cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
 & "country.name, country.population, country.continent " _
 & "FROM country, city ORDER BY country.continent, country.name"
 cmd.Connection = conn

 myAdapter.SelectCommand = cmd
 myAdapter.Fill(myData)

 myData.WriteXml("C:\dataset.xml", XmlWriteMode.WriteSchema)
Catch ex As Exception
 MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

#### C# Example

```

DataSet myData = new DataSet();
MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;
MySQL.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();
myAdapter = new MySQL.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
 "country.name, country.population, country.continent " +
 "FROM country, city ORDER BY country.continent, country.name";
 cmd.Connection = conn;

 myAdapter.SelectCommand = cmd;
 myAdapter.Fill(myData);

 myData.WriteXml(@"C:\dataset.xml", XmlWriteMode.WriteSchema);
}
catch (MySQL.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show(ex.Message, "Report could not be created",
 MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

The resulting XML file can be used as an ADO.NET XML datasource when designing your report.

If you choose to design your reports using Connector/ODBC, it can be downloaded from [dev.mysql.com](http://dev.mysql.com).

### 29.2.5.5.3. Creating the Report

For most purposes the Standard Report wizard should help with the initial creation of a report. To start the wizard, open Crystal Reports and choose the New > Standard Report option from the File menu.

The wizard will first prompt you for a data source. If you are using Connector/ODBC as your data source, use the OLEDB provider for ODBC option from the OLE DB (ADO) tree instead of the ODBC (RDO) tree when choosing a data source. If using a saved data set, choose the ADO.NET (XML) option and browse to your saved data set.

The remainder of the report creation process is done automatically by the wizard.

After the report is created, choose the Report Options... entry of the File menu. Un-check the Save Data With Report option. This prevents saved data from interfering with the loading of data within our application.

### 29.2.5.5.4. Displaying the Report

To display a report we first populate a data set with the data needed for the report, then load the report and bind it to the data set. Finally we pass the report to the crViewer control for display to the user.

The following references are needed in a project that displays a report:

- CrystalDecisions.CrystalReports.Engine
- CrystalDecisions.ReportSource
- CrystalDecisions.Shared
- CrystalDecisions.Windows.Forms

The following code assumes that you created your report using a data set saved using the code shown in [Section 29.2.5.5.2, "Creating a Data Source"](#), and have a crViewer control on your form named `myViewer`.

#### Visual Basic Example

```

Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySQL.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = _

```

```

"server=127.0.0.1;" _
& "uid=root;" _
& "pwd=12345;" _
& "database=test"

Try
 conn.Open()

 cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
 & "country.name, country.population, country.continent " _
 & "FROM country, city ORDER BY country.continent, country.name"
 cmd.Connection = conn

 myAdapter.SelectCommand = cmd
 myAdapter.Fill(myData)

 myReport.Load(".\world_report.rpt")
 myReport.SetDataSource(myData)
 myViewer.ReportSource = myReport
Catch ex As Exception
 MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

### C# Example

```

using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
 "country.name, country.population, country.continent " +
 "FROM country, city ORDER BY country.continent, country.name";
 cmd.Connection = conn;

 myAdapter.SelectCommand = cmd;
 myAdapter.Fill(myData);

 myReport.Load(@".\world_report.rpt");
 myReport.SetDataSource(myData);
 myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show(ex.Message, "Report could not be created",
 MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

A new data set is generated using the same query used to generate the previously saved data set. Once the data set is filled, a `ReportDocument` is used to load the report file and bind it to the data set. The `ReportDocument` is then passed as the `ReportSource` of the `crViewer`.

This same approach is taken when a report is created from a single table using `Connector/ODBC`. The data set replaces the table used in the report and the report is displayed properly.

When a report is created from multiple tables using `Connector/ODBC`, a data set with multiple tables must be created in our application. This allows each table in the report data source to be replaced with a report in the data set.

We populate a data set with multiple tables by providing multiple `SELECT` statements in our `MySqlCommand` object. These `SELECT` statements are based on the SQL query shown in Crystal Reports in the Database menu's Show SQL Query option. Assume the following query:

```

SELECT `country`.`Name`, `country`.`Continent`, `country`.`Population`, `city`.`Name`, `city`.`Population`
FROM `world`.`country` `country` LEFT OUTER JOIN `world`.`city` `city` ON `country`.`Code`=`city`.`CountryCode`
ORDER BY `country`.`Continent`, `country`.`Name`, `city`.`Name`

```

This query is converted to two `SELECT` queries and displayed with the following code:

### Visual Basic Example

```

Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data

```

```
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=world"

Try
 conn.Open()
 cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER BY countrycode, name;" _
 & "SELECT name, population, code, continent FROM country ORDER BY continent, name"
 cmd.Connection = conn

 myAdapter.SelectCommand = cmd
 myAdapter.Fill(myData)

 myReport.Load(".\world_report.rpt")
 myReport.Database.Tables(0).SetDataSource(myData.Tables(0))
 myReport.Database.Tables(1).SetDataSource(myData.Tables(1))
 myViewer.ReportSource = myReport
Catch ex As Exception
 MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

### C# Example

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER " +
 "BY countrycode, name; SELECT name, population, code, continent FROM " +
 "country ORDER BY continent, name";
 cmd.Connection = conn;

 myAdapter.SelectCommand = cmd;
 myAdapter.Fill(myData);

 myReport.Load(@".\world_report.rpt");
 myReport.Database.Tables(0).SetDataSource(myData.Tables(0));
 myReport.Database.Tables(1).SetDataSource(myData.Tables(1));
 myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show(ex.Message, "Report could not be created",
 MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

It is important to order the [SELECT](#) queries in alphabetical order, as this is the order the report will expect its source tables to be in. One `SetDataSource` statement is needed for each table in the report.

This approach can cause performance problems because Crystal Reports must bind the tables together on the client-side, which will be slower than using a pre-saved data set.

## 29.2.5.6. Handling Date and Time Information in Connector/.NET

### 29.2.5.6.1. Introduction

MySQL and the .NET languages handle date and time information differently, with MySQL allowing dates that cannot be represented by a .NET data type, such as '0000-00-00 00:00:00'. These differences can cause problems if not properly handled.

In this section we will demonstrate how to properly handle date and time information when using Connector/.NET.

### 29.2.5.6.2. Problems when Using Invalid Dates

The differences in date handling can cause problems for developers who use invalid dates. Invalid MySQL dates cannot be loaded into native .NET `DateTime` objects, including `NULL` dates.

Because of this issue, .NET `DataSet` objects cannot be populated by the `Fill` method of the `MySqlDataAdapter` class as invalid dates will cause a `System.ArgumentOutOfRangeException` exception to occur.

### 29.2.5.6.3. Restricting Invalid Dates

The best solution to the date problem is to restrict users from entering invalid dates. This can be done on either the client or the server side.

Restricting invalid dates on the client side is as simple as always using the .NET `DateTime` class to handle dates. The `DateTime` class will only allow valid dates, ensuring that the values in your database are also valid. The disadvantage of this is that it is not useful in a mixed environment where .NET and non .NET code are used to manipulate the database, as each application must perform its own date validation.

Users of MySQL 5.0.2 and higher can use the new `traditional` SQL mode to restrict invalid date values. For information on using the `traditional` SQL mode, see [Section 5.1.7, "SQL Modes"](#).

### 29.2.5.6.4. Handling Invalid Dates

Although it is strongly recommended that you avoid the use of invalid dates within your .NET application, it is possible to use invalid dates by means of the `MySqlDateTime` datatype.

The `MySqlDateTime` datatype supports the same date values that are supported by the MySQL server. The default behavior of Connector/NET is to return a .NET `DateTime` object for valid date values, and return an error for invalid dates. This default can be modified to cause Connector/NET to return `MySqlDateTime` objects for invalid dates.

To instruct Connector/NET to return a `MySqlDateTime` object for invalid dates, add the following line to your connection string:

```
Allow Zero Datetime=True
```

Please note that the use of the `MySqlDateTime` class can still be problematic. The following are some known issues:

1. Data binding for invalid dates can still cause errors (zero dates like 0000-00-00 do not seem to have this problem).
2. The `ToString` method return a date formatted in the standard MySQL format (for example, 2005-02-23 08:50:25). This differs from the `ToString` behavior of the .NET `DateTime` class.
3. The `MySqlDateTime` class supports `NULL` dates, while the .NET `DateTime` class does not. This can cause errors when trying to convert a `MySqlDateTime` to a `DateTime` if you do not check for `NULL` first.

Because of the known issues, the best recommendation is still to use only valid dates in your application.

### 29.2.5.6.5. Handling NULL Dates

The .NET `DateTime` datatype cannot handle `NULL` values. As such, when assigning values from a query to a `DateTime` variable, you must first check whether the value is in fact `NULL`.

When using a `MySqlDataReader`, use the `.IsDBNull` method to check whether a value is `NULL` before making the assignment:

Visual Basic Example

```
If Not myReader.IsDBNull(myReader.GetOrdinal("mytime")) Then
 myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"))
Else
 myTime = DateTime.MinValue
End If
```

C# Example

```
if (! myReader.IsDBNull(myReader.GetOrdinal("mytime")))
 myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"));
else
 myTime = DateTime.MinValue;
```

`NULL` values will work in a data set and can be bound to form controls without special handling.

### 29.2.5.7. Frequently Asked Questions

The following details a number of frequently asked questions about Connector/NET.

#### Questions

- [30.2.5.7.1](#): How do I obtain the value of an auto-incremented column?

#### Questions and Answers

##### 30.2.5.7.1: How do I obtain the value of an auto-incremented column?

When using the `commandBuilder` you should make sure that you set the `ReturnGeneratedIdentifiers` property to `true`.

Then, you can use an active view on a table to access the updated ID. For example:

```

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
da = new MySql.Data.MySqlClient.MySqlDataAdapter();
cmdBuilder = new MySql.Data.MySqlClient.MySqlCommandBuilder();
SystemDataDataSet = new System.Data.DataSet();
SystemDataDataView = new System.Data.DataView();
...
cmd.Connection = conn;
cmd.CommandText = "SELECT * FROM contacts";
da.SelectCommand = cmd;
da.Fill(SystemDataDataSet, "contacts");
cmdBuilder.DataAdapter = da;
cmdBuilder.ReturnGeneratedIdentifiers = true;
cmdBuilder.DataAdapter.SelectCommand.CommandText = "SELECT * FROM contacts";
cmdBuilder.RefreshSchema();

SystemDataDataView = SystemDataDataSet.Tables["contacts"].DefaultView;

SystemDataDataRow = SystemDataDataView.Table.NewRow();
SystemDataDataRow["status"] = 1;

SystemDataDataView.Table.Rows.Add(SystemDataDataRow);
da.Update(SystemDataDataSet, "contacts");
System.Console.WriteLine("ID after update: " + SystemDataDataRow["id"]);

```

The `SystemDataDataRow` object in this instance provides the interface to the updated auto-increment value in the `id` column.

## 29.2.6. Connector/NET Support

The developers of Connector/NET greatly value the input of our users in the software development process. If you find Connector/NET lacking some feature important to you, or if you discover a bug and need to file a bug report, please use the instructions in [Section 1.7, "How to Report Bugs or Problems"](#).

### 29.2.6.1. Connector/NET Community Support

- Community support for Connector/NET can be found through the forums at <http://forums.mysql.com>.
- Community support for Connector/NET can also be found through the mailing lists at <http://lists.mysql.com>.
- Paid support is available from MySQL AB. Additional information is available at <http://www.mysql.com/support/>.

### 29.2.6.2. How to report Connector/NET Problems or Bugs

If you encounter difficulties or problems with Connector/NET, contact the Connector/NET community [Section 29.2.6.1, "Connector/NET Community Support"](#).

You should first try to execute the same SQL statements and commands from the `mysql` client program or from `admindemo`. This helps you determine whether the error is in Connector/NET or MySQL.

If reporting a problem, you should ideally include the following information with the email:

- Operating system and version
- Connector/NET version
- MySQL server version
- Copies of error messages or other unexpected output
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

If you believe the problem to be a bug, then you must report the bug through <http://bugs.mysql.com/>.

### 29.2.6.3. Connector/NET Change History

The Connector/NET Change History (Changelog) is located with the main Changelog for MySQL. See [Section C.3, “MySQL Connector/NET Change History”](#).

## 29.3. MySQL Visual Studio Plugin

The MySQL Visual Studio Plugin is a DDEX provider; a plug-in for Visual Studio 2005 that allows developers to maintain database structures, and supports built-in data-driven application development tools.

The current version of the MySQL Visual Studio Plugin includes only database maintenance tools. Data-driven application development tools are not supported.

The MySQL DDEX Provider operates as a standard extension to the Visual Studio Data Designer functionality available through the Server Explorer menu of Visual Studio 2005, and enables developers to create database objects and data within a MySQL database.

The MySQL Visual Studio Plugin is designed to work with MySQL version 5.0, but is also compatible with MySQL 4.1.1 and provides limited compatibility with MySQL 5.1.

### 29.3.1. Installing the MySQL Visual Studio Plugin

The MySQL Visual Studio Plugin requires one of Visual Studio 2005 Standard, Professional or Team Developer Edition to be installed. Other editions of Visual Studio 2005 are not supported.

#### Note

Starting with Connector/NET 5.1.2, the Visual Studio Plugin is included in the installation. If you have installed Connector/NET 5.1.2, then you do not need to separately install the Visual Studio Plugin.

Here is the list of components that should already be installed before starting the installation of the MySQL Visual Studio Plugin:

- Visual Studio 2005 Standard, Professional or Team Developer Edition.
- MySQL Server 4.1.1 or later (either installed on the same machine, or a separate server).
- MySQL Connector/NET 5.0.

#### Note

When installing Connector/NET you must ensure that the connector is installed into the Global Assembly Cache (GAC). The Connector/NET installer handles this for you automatically, but in a custom installation the option may have been disabled.

The user used to connect to the MySQL server must have the following privileges to use the functionality provided by the MySQL Visual Studio Plugin:

- The `SELECT` privilege for the `INFORMATION_SCHEMA` database.
- The `EXECUTE` privilege for the `SHOW CREATE TABLE` statement.
- The `SELECT` privilege for the `mysql.proc` table (required for operations with stored procedures and functions).

- The `SELECT` privilege for the `mysql.func` table (required for operations with User Defined Functions (UDF)).
- The `EXECUTE` privilege for the `SHOW ENGINE STATUS` statement (required for retrieving extended error information).
- Appropriate privileges for performed operations (e.g. the `SELECT` privilege is required to browse data from a table etc.).

The MySQL Visual Studio Plugin is delivered as a MSI package that can be used to install, uninstall or reinstall the Provider. If you are not using Windows XP or Windows Server 2003 you upgrade the Windows Installer system to the latest version (see <http://support.microsoft.com/default.aspx?scid=kb;EN-US;292539> for details).

The MSI-package is named `MySQL.VisualStudio.msi`. To install the MySQL Visual Studio Plugin, right click on the MSI file and select `INSTALL`. The installation process is as follow:

1. The standard Welcome dialog is opened. Click Next to continue installation.
2. The License agreement (GNU GPL) window is opened. Accept the agreement and click NEXT to continue.
3. The destination folder choice dialog is opened. Here you can point out the folder where the MySQL Visual Studio Plugin will be installed. The default destination folder is `%ProgramFilesDir%\MySQL\MySQL DDEX Data Provider`, where `%ProgramFilesDir%` is the Program Files folder of the installation machine. After choosing the destination folder, click NEXT to continue.
4. The installer will ask to confirm that installation. Click Install to start installation process.
5. The installation will now take place. At the end of this step the Visual Studio command table is rebuilt (this process may take several minutes).
6. Once installation is complete, click FINISH to end the installation process.

To uninstall the MySQL Visual Studio Plugin, you can use either Add/Remove Programs component of the Control Panel or the same MSI-package. Choose the `REMOVE` option, and the Provider will be uninstalled automatically.

To repair the Provider, right click the MSI-package and choose the `REPAIR` option. The MySQL Visual Studio Plugin will be repaired automatically.

The installation package includes the following files:

- `MySQL.VisualStudio.dll` — the MySQL DDEX Provider assembly.
- `MySQL.Data.dll` — the assembly containing the MySQL Connector .NET which is used by the Provider.
- `MySql.VisualStudio.dll.config` — the configuration file for the MySQL Visual Studio Plugin. This file contains default values for the provider GUI layout.

### Note

Do not remove this file before the first use of the Provider.

- `Register.reg` — the file with registry entries that can be used to register the MySQL DDEX Provider in the case of the manual installation.
- `Install.js` — the script used to register the Connector .NET as an ADO.NET data provider in the machine.config file.
- `Release notes.doc` — the document with release notes.

To install the Provider manually, copy all files of the installation package in a desired folder, then set the full path to the Provider assembly as a value of the CodeBase entry. For example:

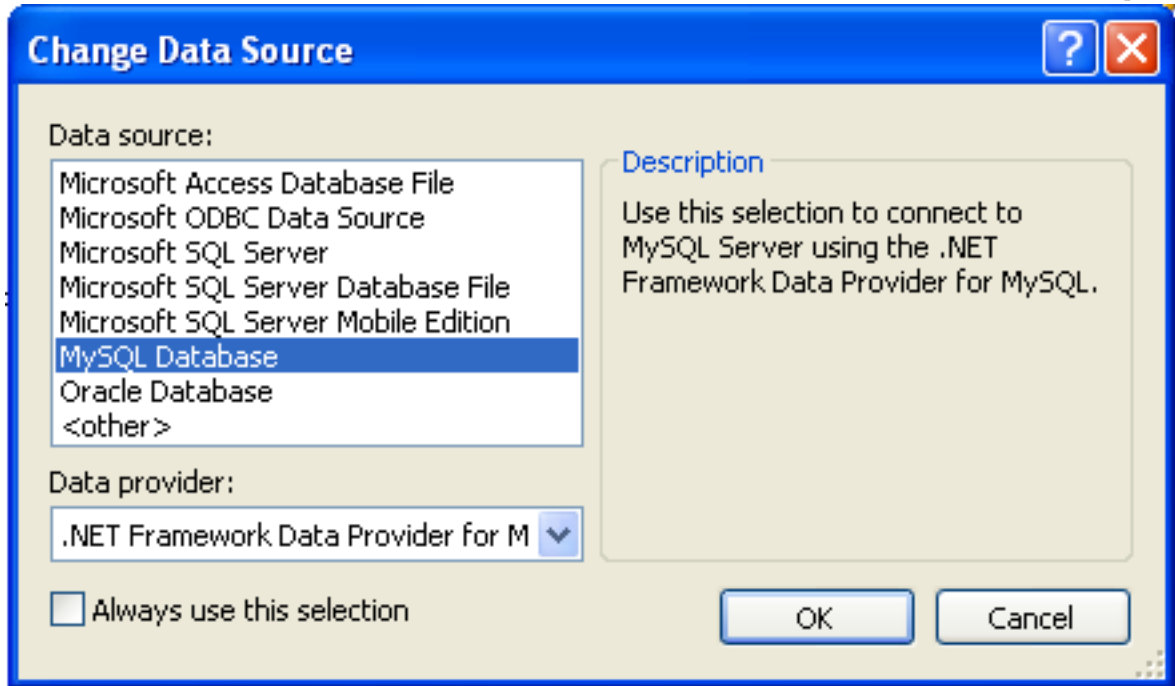

```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\VisualStudio\8.0\Packages\{79A115C9-B133-4891-9E7B-242509DAD272}]@="MySql.Data.
"InprocServer32"="C:\WINNT\system32\mscoree.dll"
"Class"="MySql.Data.VisualStudio.MySqlDataProviderPackage"
"CodeBase"="C:\MySqlDdexProvider\MySql.VisualStudio.dll"
```

Then import information from the Register.reg file to the registry by clicking of the file. At the confirmation dialog choose Yes. Next you must run the command `devenv.exe /setup` within a Command Prompt to rebuild the Visual Studio command table.

## 29.3.2. Creating a connection to the MySQL server

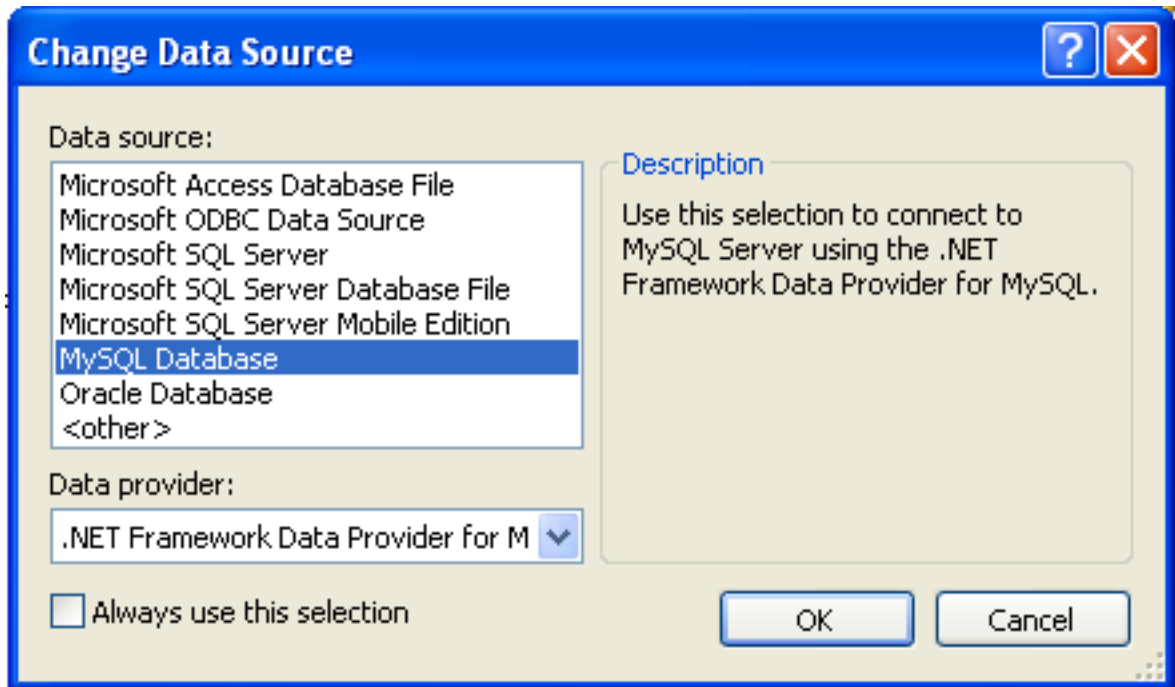

Once the MySQL Visual Studio Plugin is installed, you can use it to create, modify and delete connections to MySQL databases. To create a connection with a MySQL database, perform the following steps:

1. Start Visual Studio 2005 and open Server Explorer window by choosing the **SERVER EXPLORER** option from the **VIEW** menu.
2. Right click on the **DATA CONNECTIONS** node and choose the **ADD CONNECTION** button.
3. The Add Connection dialog is opened. Press the **CHANGE** button to choose MySQL Database as a data source.
4. Change Data Source dialog is opened. Choose MySQL Database in the list of data sources (or the **other** option, if MySQL Database is absent), and then choose **.NET FRAMEWORK DATA PROVIDER FOR MYSQL** in the combo box of data providers.

Press OK to confirm your choice.

5. Enter the connection settings: the server host name (for example, localhost if the MySQL server is installed on the local machine), the user name, the password, and the default database schema. Note that you must specify the default schema name to open the connection.

6. You can also set the port to connect with the MySQL server by pressing the **ADVANCED** button. To test a connection with the MySQL server, set the server host name, the user name, and the password, and press the **TEST CONNECTION** button. If the test fails, check the connection values that you have supplied are correct and that the corresponding user and privileges have been configured on the MySQL server.
7. After you set all settings and test the connection, press **OK**. The newly created connection is displayed in Server Explorer. Now you can work with the MySQL server through standard Server Explorer interface.

After a connection is successfully established, all the connection settings are saved. When you next open Visual Studio, the connection to the MySQL server will appear within Server Explorer so that you can re-establish a connection to the MySQL server.

To modify and delete a connection, use the **SERVER EXPLORER** context menu for the corresponding node. You can modify any of the settings just by overwriting the existing values with new ones. Note that a connection should be modified or deleted only if no active editor for its objects is opened. Otherwise your data could be lost.

### 29.3.3. Using the MySQL Visual Studio Plugin

To work with a MySQL server using the MySQL Visual Studio Plugin, open the Visual Studio 2005, open the **SERVER EXPLORER**, and select the required connection. The working area of the MySQL Visual Studio Plugin consists of three parts.

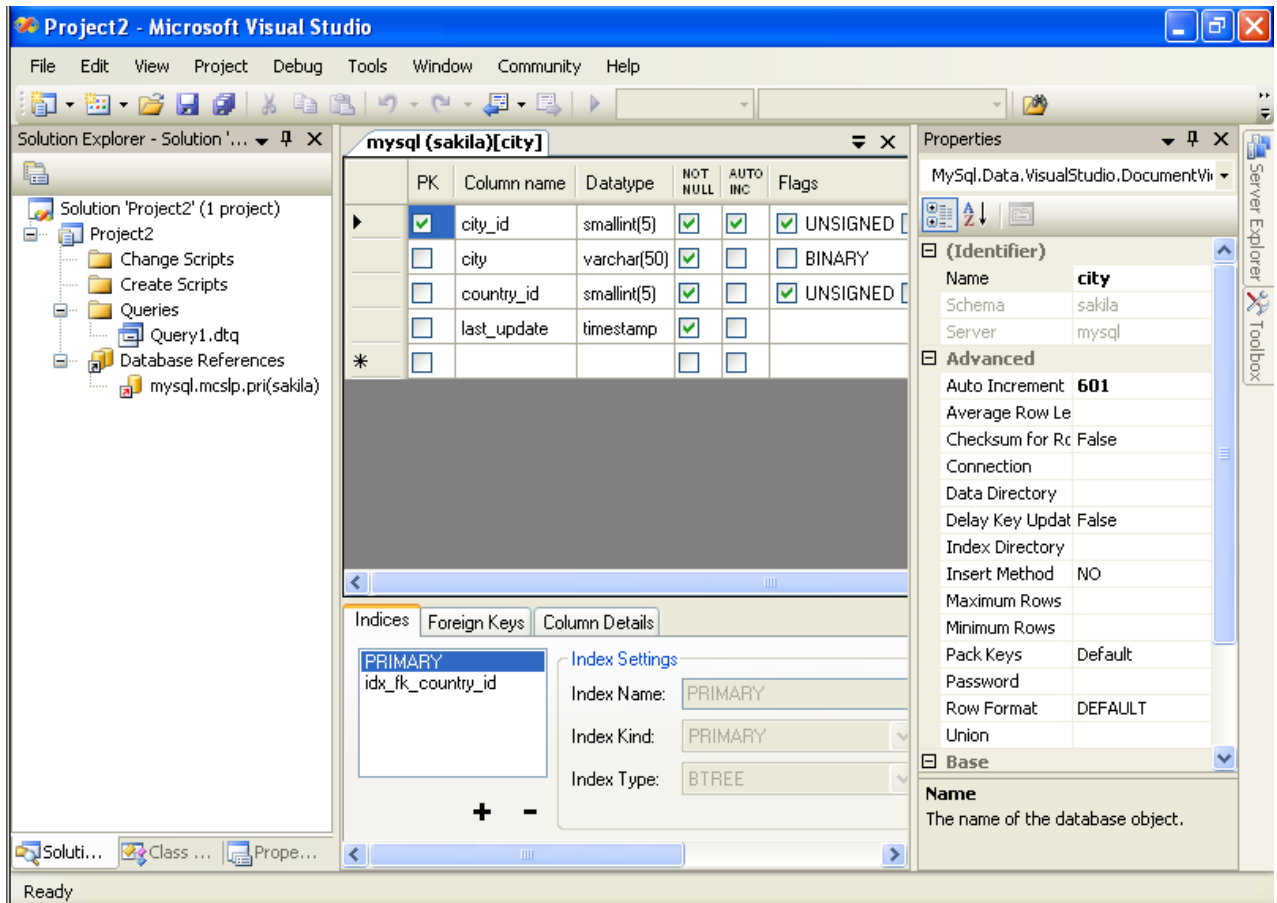

- Database objects (tables, views, stored routines, triggers, and user defined functions) are displayed in the Server Explorer tree. Here you can choose an object and edit its properties and definition.
- Properties of a selected database object are displayed in the **PROPERTIES** panel. Certain properties can be edited directly within this window.
- The editor panel provides direct access to the SQL statement and definition of specific objects. For example, the SQL statements within a stored procedure definition are shown and edited within this panel.

### 29.3.3.1. Editing Tables

The Table Editor can be accessed through a mouse action on table-type node of Server Explorer. To create a new table, right click on the **TABLES** node (under the connection node) and choose the **CREATE TABLE** command from a context menu. To modify an existing table, double click on a node of the table you wish to modify, or right click on this node and choose the **ALTER TABLE** command from a context menu. Either of the commands opens the Table Editor.

The MySQL Visual Studio Plugin Table Editor is implemented in a similar fashion to the standard Query Browser Table Editor, but with minor differences.

The Table Editor consists of the following parts:

- Columns Editor — for column creation, modification and deletion.
- Indexes tab — for table/column index management.
- Foreign Keys tab — for configuration of foreign keys.
- Column Details tab — used to set advanced column options.
- Properties window — used to set table properties.

To save changes you have made in the Table Editor, use either Save or Save All buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. Before changes are saved, a confirmation dialog will be displayed to confirm that you want to update the corresponding object within the MySQL database.

### 29.3.3.1.1. Column Editor

You can use the Column Editor to set or change the name, data type, default value and other properties of a table column. To set the properties of an individual column, select the column using the mouse. Alternatively, you can move through the grid using **Tab** and **Shift+Tab** keys.

- To set or change the name, data type, default value and comment of a column, select the appropriate cell and edit the desired value.
- To set or unset flag-type column properties (i.e., primary key, **NOT NULL**, auto-incremented, flags), check or uncheck the corresponding checkboxes. Note that the available column flags will depend on the columns data type.
- To reorder columns, index columns or foreign key columns in the Column Editor, select the whole column you wish to reorder by clicking on the selector column at the left of the column grid. Then move the column by using **Ctrl+Up** (to move the

column up) and **Ctrl+Down** (to move the column down) keys.

- To delete a column, select it by clicking on the selector column at the left of the column grid, then press the **Delete** button on a keyboard.

### 29.3.3.1.2. Indexes tab

Index management is performed via the Indexes tab.

- To add an index, press the + button and set the properties in the **INDEX SETTINGS** groupbox at the right. You can set the index name, index kind, index type and a set of index columns.
- To remove an index, select the index from the list and press the - button.
- To change index settings, select the index from the list; detailed information about the index is displayed in the **INDEX SETTINGS** panel.

You cannot change a table column to an index column using drag and drop. Instead, you can add new index columns to a table and set their table columns by using the embedded editor within the Indexes tab

### 29.3.3.1.3. Foreign Keys tab

Foreign Key management is performed via the Foreign Keys tab.

- To add a foreign key, press the + button and set properties in the **FOREIGN KEYS SETTINGS** panel. You can set the foreign key name, referenced table name, foreign key columns and actions on update and delete.
- To remove a foreign key, select the foreign key and press the - button.
- To change foreign key settings, select the foreign key and use the **FOREIGN KEYS SETTINGS** panel to edit the properties.
- When a foreign key is changed, the MySQL Visual Studio Plugin generates two queries: the first query drops the changed keys and the second one recreates the new values. The reason for such a behavior is to avoid the [Bug#8377](#) and [Bug#8919](#).

#### Note

If changed values are for some reason inconsistent and cause the second query to fail, all affected foreign keys will be dropped. If this is the case, the MySQL Visual Studio Plugin will mark them as new in the Table Editor, and you will have to recreate them later. But if you close the Table Editor without saving, these foreign keys will be lost.

### 29.3.3.1.4. Column Details tab

The Column Details tab can be used to set column options. Besides the main column properties that are presented in the Column Editor, in the Column Details tab you can set two additional properties options: the character set and the collation sequence.

### 29.3.3.1.5. Table Properties window

There is no separate tab for table options and advanced options. All table options can be browsed and changed using the **PROPERTIES** window of Visual Studio 2005.

The following table properties can be set:

- **AUTO INCREMENT**
- **AVERAGE ROW LENGTH**
- **CHARACTER SET**
- **CHECKSUM FOR ROWS**
- **COLLATION**
- **COMMENT**
- **CONNECTION**

- **DATA DIRECTORY**
- **DELAY KEY UPDATES**
- **ENGINE**
- **INDEX DIRECTORY**
- **INSERT METHOD**
- **MAXIMUM ROWS**
- **MINIMUM ROWS**
- **NAME**
- **PACK KEYS**
- **PASSWORD**
- **ROW FORMAT**
- **UNION**

Some of these properties can have arbitrary text values, others accept values from a predefined set.

The properties **SCHEMA** and **SERVER** are read only.

### 29.3.3.2. Editing Table Data

The Table Data Editor, allows a user to browse, create and edit data of tables. The Table Data Editor is implemented as a simple data grid with auto generated columns.

To access the Table Data Editor, right click on a node representing the table or view in Server Explorer. From the nodes context menu, choose the **BROWSE** or **EDIT DATA** command. For tables and updatable views, this command opens the Table Data Editor in edit mode. For non-updatable views, this command opens the Table Data Editor in read-only mode.

When in the edit mode, you can modify table data by modifying the displayed table contents directly. To add a row, set desired values in the last row of the grid. To modify values, set new values in appropriate cells. To delete a row, select it by clicking on the selector column at the left of the grid, then press the **DELETE** button.

To save changes you have made in the Table Data Editor, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database.

### 29.3.3.3. Editing Views

To create a new view, right click the Views node under the connection node in Server Explorer. From the nodes context menu, choose the **CREATE VIEW** command. This command opens the SQL Editor.

To modify an existing view, double click on a node of the view you wish to modify, or right click on this node and choose the **ALTER VIEW** command from a context menu. Either of the commands opens the SQL Editor.

To create or alter the view definition using SQL Editor, type the appropriate SQL statement in the SQL Editor.

#### **Note**

You should enter only the defining statement itself, without the **CREATE VIEW AS** preface.

All other view properties can be set in the **PROPERTIES** window. These properties are:

- **ALGORITHM**
- **CHECK OPTION**
- **DEFINER**
- **NAME**
- **SECURITY TYPE**

Some of these properties can have arbitrary text values, others accept values from a predefined set.

The properties **IS UPDATABLE**, **SCHEMA** and **SERVER** are read-only.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database.

#### 29.3.3.4. Editing Stored Procedures and Functions

To create a new stored procedure, right click the Stored Procedures node under the connection node in Server Explorer. From the nodes context menu, choose the **CREATE ROUTINE** command. This command opens the SQL Editor.

To create a new stored function, right click the **FUNCTIONS** node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE ROUTINE** command.

To modify an existing stored routine (procedure or function), double click on a node of the routine you wish to modify, or right click on this node and choose the **ALTER ROUTINE** command from a context menu. Either of the commands opens the SQL Editor.

To create or alter the routine definition using SQL Editor, type this definition in the SQL Editor using standard SQL.

All other routine properties can be set in the **PROPERTIES** window. These properties are:

- Comment
- Data Access
- Definer
- Is Deterministic
- Security Type

Some of these properties can have arbitrary text values, others accept values only from a predefined set.

Also you can set all the options directly in the SQL Editor, using the standard **CREATE PROCEDURE** or **CREATE FUNCTION** statement. However, it is recommended to use the **PROPERTIES** window instead.

#### Note

You should never add the **CREATE** preface to the routine definition.

The properties **NAME**, **SCHEMA** and **SERVER** in the **PROPERTIES** window are read-only. Set or change the procedure name in the SQL editor.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database..

#### 29.3.3.5. Editing Triggers

To create a new trigger, right click on a node of a table for which you wish to add a trigger. From the node's context menu, choose the **CREATE TRIGGER** command. This command opens the SQL Editor.

To modify an existing trigger, double click on a node of the trigger you wish to modify, or right click on this node and choose the **ALTER TRIGGER** command from a context menu. Either of the commands opens the SQL Editor.

To create or alter the trigger definition using SQL Editor, type the trigger statement in the SQL Editor using standard SQL.

#### Note

You should enter only the trigger statement, that is the part of the **CREATE TRIGGER** query that is placed after the **FOR EACH ROW** clause.

All other trigger properties are set in the **PROPERTIES** window. These properties are:

- **DEFINER**
- **EVENT MANIPULATION**

- **NAME**
- **TIMING**

Some of these properties can have arbitrary text values, others accept values only from a predefined set.

The properties **EVENT TABLE**, **SCHEMA** and **SERVER** in the **PROPERTIES** window are read-only.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database.

### 29.3.3.6. Editing User Defined Functions (UDF)

To create a new User Defined Function (UDF), right click the UDFs node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE UDF** command. This command opens the UDF Editor.

To modify an existing UDF, double click on a node of the UDF you wish to modify, or right click on this node and choose the **Alter UDF** command from a context menu. Either of the commands opens the UDF Editor.

The UDF editor allows you to set the following properties through the properties panel:

- **NAME**
- **SO-NAME (DLL NAME)**
- **RETURN TYPE**
- **IS AGGREGATE**

The property **Server** in the **PROPERTIES** window is read-only.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database.

### 29.3.3.7. Dropping database objects

Tables, views, stored routines, triggers, and UDFs can be dropped with the appropriate **DROP** command from its context menu: **DROP TABLE**, **DROP VIEW**, **DROP ROUTINE**, **DROP TRIGGER**, **DROP UDF**.

You will be asked to confirm the execution of the corresponding drop query in a confirmation dialog.

Dropping of multiple objects is not supported.

### 29.3.3.8. Cloning database objects

Tables, views, stored procedures and functions can be cloned with the appropriate **CLONE** command from its context menu: **CLONE TABLE**, **CLONE VIEW**, **CLONE ROUTINE**. The clone commands open the corresponding editor for a new object: the **TABLE EDITOR** for cloning a table and the SQL Editor for cloning a view or a routine.

To save the cloned object, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. A confirmation dialog will confirm whether you want the changes saved to the database.

## 29.3.4. Visual Studio Plugin Support

If you have a comment, or if you discover a bug, please, use our MySQL bug tracking system (<http://bugs.mysql.com>) to report problem or add your suggestion.

### 29.3.4.1. Visual Studio Plugin FAQ

#### Questions

- **30.3.4.1.1:** When creating a connection, typing the connection details causes the connection window to immediately close.

#### Questions and Answers

**30.3.4.1.1: When creating a connection, typing the connection details causes the connection window to immediately close.**

There are known issues with versions of Connector/NET earlier than 5.0.2. Connector/NET 1.0.x is known not to work. If you have any of these versions installed, or have previously upgraded from an earlier version, uninstall Connector/NET completely and then install Connector/NET 5.0.2.

## 29.4. MySQL Connector/J

MySQL provides connectivity for client applications developed in the Java programming language via a JDBC driver, which is called MySQL Connector/J.

MySQL Connector/J is a JDBC Type 4 driver. Different versions are available that are compatible with the JDBC-3.0 and JDBC-4.0 specifications. The Type 4 designation means that the driver is pure-Java implementation of the MySQL protocol and does not rely on the MySQL client libraries.

Although JDBC is useful by itself, we would hope that if you are not familiar with JDBC that after reading the first few sections of this manual, that you would avoid using naked JDBC for all but the most trivial problems and consider using one of the popular persistence frameworks such as [Hibernate](#), [Spring's JDBC templates](#) or [Ibatis SQL Maps](#) to do the majority of repetitive work and heavier lifting that is sometimes required with JDBC.

This section is not designed to be a complete JDBC tutorial. If you need more information about using JDBC you might be interested in the following online tutorials that are more in-depth than the information presented here:

- [JDBC Basics](#) — A tutorial from Sun covering beginner topics in JDBC
- [JDBC Short Course](#) — A more in-depth tutorial from Sun and JGuru

### Key topics:

- For help with connection strings, connection options setting up your connection through JDBC, see [Section 29.4.4.1, “Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J”](#).
- For tips on using Connector/J and JDBC with generic J2EE toolkits, see [Section 29.4.5.2, “Using Connector/J with J2EE and Other Java Frameworks”](#).
- Developers using the Tomcat server platform, see [Section 29.4.5.2.2, “Using Connector/J with Tomcat”](#).
- Developers using JBoss, see [Section 29.4.5.2.3, “Using Connector/J with JBoss”](#).
- Developers using Spring, see [Section 29.4.5.2.4, “Using Connector/J with Spring”](#).

### MySQL Enterprise

MySQL Enterprise subscribers will find more information about using JDBC with MySQL in the Knowledge Base articles about [JDBC](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

### 29.4.1. Connector/J Versions

There are currently four versions of MySQL Connector/J available:

- Connector/J 5.1 is the Type IV pure Java JDBC driver and provides compatibility with all the functionality of MySQL, including 4.1, 5.0, 5.1 and the 6.0 alpha release featuring the new Falcon storage engine. Connector/J 5.1 provides ease of development features, including auto-registration with the Driver Manager, standardized validity checks, categorized SQLExceptions, support for the JDBC-4.0 XML processing, per connection client information, [NCHAR](#), [NVARCHAR](#) and [NCLLOB](#) types. This release also includes all bug fixes up to and including Connector/J 5.0.6.
- Connector/J 5.0 provides support for all the functionality offered by Connector/J 3.1 and includes distributed transaction (XA) support.
- Connector/J 3.1 was designed for connectivity to MySQL 4.1 and MySQL 5.0 servers and provides support for all the functionality in MySQL 5.0 except distributed transaction (XA) support.
- Connector/J 3.0 provides core functionality and was designed with connectivity to MySQL 3.x or MySQL 4.1 servers, although it will provide basic compatibility with later versions of MySQL. Connector/J 3.0 does not support server-side prepared state-

ments, and does not support any of the features in versions of MySQL later than 4.1.

The current recommended version for Connector/J is 5.1. This guide covers all three connector versions, with specific notes given where a setting applies to a specific option.

### 29.4.1.1. Java Versions Supported

MySQL Connector/J supports Java-2 JVMs, including:

- JDK 1.2.x (only for Connector/J 3.1.x or earlier)
- JDK 1.3.x
- JDK 1.4.x
- JDK 1.5.x
- JDK 1.6.x

If you are building Connector/J from source using the source distribution (see [Section 29.4.2.4, “Installing from the Development Source Tree”](#)) then you must use JDK 1.4.x or newer to compile the Connector package. For Connector/J 5.1 you must use JDK-1.6.x.

MySQL Connector/J does not support JDK-1.1.x or JDK-1.0.x.

Because of the implementation of `java.sql.Savepoint`, Connector/J 3.1.0 and newer will not run on JDKs older than 1.4 unless the class verifier is turned off (by setting the `-Xverify:none` option to the Java runtime). This is because the class verifier will try to load the class definition for `java.sql.Savepoint` even though it is not accessed by the driver unless you actually use savepoint functionality.

Caching functionality provided by Connector/J 3.1.0 or newer is also not available on JVMs older than 1.4.x, as it relies on `java.util.LinkedHashMap` which was first available in JDK-1.4.0.

## 29.4.2. Connector/J Installation

You can install the Connector/J package using two methods, using either the binary or source distribution. The binary distribution provides the easiest methods for installation; the source distribution enables you to customize your installation further. With either solution, you must manually add the Connector/J location to your Java `CLASSPATH`.

If you are upgrading from a previous version, read the upgrade information before continuing. See [Section 29.4.2.3, “Upgrading from an Older Version”](#).

### 29.4.2.1. Installing Connector/J from a Binary Distribution

The easiest method of installation is to use the binary distribution of the Connector/J package. The binary distribution is available either as a Tar/Gzip or Zip file which you must extract to a suitable location and then optionally make the information about the package available by changing your `CLASSPATH` (see [Section 29.4.2.2, “Installing the Driver and Configuring the CLASSPATH”](#)).

MySQL Connector/J is distributed as a .zip or .tar.gz archive containing the sources, the class files, and the JAR archive named `mysql-connector-java-[version]-bin.jar`, and starting with Connector/J 3.1.8 a debug build of the driver in a file named `mysql-connector-java-[version]-bin-g.jar`.

Starting with Connector/J 3.1.9, the `.class` files that constitute the JAR files are only included as part of the driver JAR file.

You should not use the debug build of the driver unless instructed to do so when reporting a problem or a bug to MySQL AB, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

You will need to use the appropriate graphical or command-line utility to extract the distribution (for example, WinZip for the .zip archive, and `tar` for the .tar.gz archive). Because there are potentially long filenames in the distribution, we use the GNU tar archive format. You will need to use GNU tar (or an application that understands the GNU tar archive format) to unpack the .tar.gz variant of the distribution.

### 29.4.2.2. Installing the Driver and Configuring the CLASSPATH

Once you have extracted the distribution archive, you can install the driver by placing `mysql-connect-`

`or-java-[version]-bin.jar` in your classpath, either by adding the full path to it to your `CLASSPATH` environment variable, or by directly specifying it with the command line switch `-cp` when starting your JVM.

If you are going to use the driver with the JDBC DriverManager, you would use `com.mysql.jdbc.Driver` as the class that implements `java.sql.Driver`.

You can set the `CLASSPATH` environment variable under UNIX, Linux or Mac OS X either locally for a user within their `.profile`, `.login` or other login file. You can also set it globally by editing the global `/etc/profile` file.

For example, under a C shell (csh, tcsh) you would add the Connector/J driver to your `CLASSPATH` using the following:

```
shell> setenv CLASSPATH /path/mysql-connector-java-[ver]-bin.jar:$CLASSPATH
```

Or with a Bourne-compatible shell (sh, ksh, bash):

```
export set CLASSPATH=/path/mysql-connector-java-[ver]-bin.jar:$CLASSPATH
```

Within Windows 2000, Windows XP and Windows Server 2003, you must set the environment variable through the System control panel.

If you want to use MySQL Connector/J with an application server such as Tomcat or JBoss, you will have to read your vendor's documentation for more information on how to configure third-party class libraries, as most application servers ignore the `CLASSPATH` environment variable. For configuration examples for some J2EE application servers, see [Section 29.4.5.2, "Using Connector/J with J2EE and Other Java Frameworks"](#). However, the authoritative source for JDBC connection pool configuration information for your particular application server is the documentation for that application server.

If you are developing servlets or JSPs, and your application server is J2EE-compliant, you can put the driver's `.jar` file in the `WEB-INF/lib` subdirectory of your webapp, as this is a standard location for third party class libraries in J2EE web applications.

You can also use the `MySQLDataSource` or `MySQLConnectionPoolDataSource` classes in the `com.mysql.jdbc.jdbc2.optional` package, if your J2EE application server supports or requires them. Starting with Connector/J 5.0.0, the `javax.sql.XADataSource` interface is implemented via the `com.mysql.jdbc.jdbc2.optional.MySQLXADataSource` class, which supports XA distributed transactions when used in combination with MySQL server version 5.0.

The various `MySQLDataSource` classes support the following parameters (through standard set mutators):

- user
- password
- serverName (see the previous section about fail-over hosts)
- databaseName
- port

### 29.4.2.3. Upgrading from an Older Version

MySQL AB tries to keep the upgrade process as easy as possible, however as is the case with any software, sometimes changes need to be made in new versions to support new features, improve existing functionality, or comply with new standards.

This section has information about what users who are upgrading from one version of Connector/J to another (or to a new version of the MySQL server, with respect to JDBC functionality) should be aware of.

#### 29.4.2.3.1. Upgrading from MySQL Connector/J 3.0 to 3.1

Connector/J 3.1 is designed to be backward-compatible with Connector/J 3.0 as much as possible. Major changes are isolated to new functionality exposed in MySQL-4.1 and newer, which includes Unicode character sets, server-side prepared statements, SQL-State codes returned in error messages by the server and various performance enhancements that can be enabled or disabled via configuration properties.

- **Unicode Character Sets** — See the next section, as well as [Section 9.1, "Character Set Support"](#), for information on this new feature of MySQL. If you have something misconfigured, it will usually show up as an error with a message similar to `Illegal mix of collations`.
- **Server-side Prepared Statements** — Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer).

Starting with version 3.1.7, the driver scans SQL you are preparing via all variants of `Connection.prepareStatement()` to determine if it is a supported type of statement to prepare on the server side, and if it is not supported by the server, it instead prepares it as a client-side emulated prepared statement. You can disable this feature by passing `emulateUnsupportedPstmts=false` in your JDBC URL.

If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the connection property `useServerPrepStmts=false`

- **Datetimes** with all-zero components (`0000-00-00 . . .`) — These values can not be represented reliably in Java. Connector/J 3.0.x always converted them to NULL when being read from a `ResultSet`.

Connector/J 3.1 throws an exception by default when these values are encountered as this is the most correct behavior according to the JDBC and SQL standards. This behavior can be modified using the `zeroDateTimeBehavior` configuration property. The allowable values are:

- `exception` (the default), which throws an `SQLException` with an `SQLState` of `S1009`.
- `convertToNull`, which returns `NULL` instead of the date.
- `round`, which rounds the date to the nearest closest value which is `0001-01-01`.

Starting with Connector/J 3.1.7, `ResultSet.getString()` can be decoupled from this behavior via `noDatetimeStringSync=true` (the default value is `false`) so that you can get retrieve the unaltered all-zero value as a `String`. It should be noted that this also precludes using any time zone conversions, therefore the driver will not allow you to enable `noDatetimeStringSync` and `useTimeZone` at the same time.

- **New SQLState Codes** — Connector/J 3.1 uses SQL:1999 SQLState codes returned by the MySQL server (if supported), which are different from the legacy X/Open state codes that Connector/J 3.0 uses. If connected to a MySQL server older than MySQL-4.1.0 (the oldest version to return SQLStates as part of the error code), the driver will use a built-in mapping. You can revert to the old mapping by using the configuration property `useSqlStateCodes=false`.
- **`ResultSet.getString()`** — Calling `ResultSet.getString()` on a BLOB column will now return the address of the `byte[]` array that represents it, instead of a `String` representation of the BLOB. BLOBs have no character set, so they can't be converted to `java.lang.Strings` without data loss or corruption.

To store strings in MySQL with LOB behavior, use one of the TEXT types, which the driver will treat as a `java.sql.Clob`.

- **Debug builds** — Starting with Connector/J 3.1.8 a debug build of the driver in a file named `mysql-connector-java-[version]-bin-g.jar` is shipped alongside the normal binary jar file that is named `mysql-connector-java-[version]-bin.jar`.

Starting with Connector/J 3.1.9, we don't ship the `.class` files unbundled, they are only available in the JAR archives that ship with the driver.

You should not use the debug build of the driver unless instructed to do so when reporting a problem or bug to MySQL AB, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

#### 29.4.2.3.2. Upgrading to MySQL Connector/J 5.1.x

- In Connector/J 5.0.x and earlier, the alias for a table in a `SELECT` statement is returned when accessing the result set metadata using `ResultSetMetaData.getColumnname()`. This behavior however is not JDBC compliant, and in Connector/J 5.1 this behavior was changed so that the original table name, rather than the alias, is returned.

The JDBC-compliant behavior is designed to let API users reconstruct the DML statement based on the metadata within `ResultSet` and `ResultSetMetaData`.

You can get the alias for a column in a result set by calling `ResultSetMetaData.getColumnLabel()`. If you want to use the old non-compliant behavior with `ResultSetMetaData.getColumnname()`, use the `useOldAliasMetadataBehavior` option and set the value to `true`.

In Connector/J 5.0.x the default value of `useOldAliasMetadataBehavior` was `true`, but in Connector/J 5.1 this was changed to a default value of `false`.

#### 29.4.2.3.3. JDBC-Specific Issues When Upgrading to MySQL Server 4.1 or Newer

- *Using the UTF-8 Character Encoding* - Prior to MySQL server version 4.1, the UTF-8 character encoding was not supported by the server, however the JDBC driver could use it, allowing storage of multiple character sets in latin1 tables on the server.

Starting with MySQL-4.1, this functionality is deprecated. If you have applications that rely on this functionality, and can not upgrade them to use the official Unicode character support in MySQL server version 4.1 or newer, you should add the following property to your connection URL:

```
useOldUTF8Behavior=true
```

- *Server-side Prepared Statements* - Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer). If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the following connection property:

```
useServerPrepStmts=false
```

#### 29.4.2.4. Installing from the Development Source Tree

##### Caution

You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL Connector/J up and running on your system, you should use a standard release distribution.

To install MySQL Connector/J from the development source tree, make sure that you have the following prerequisites:

- Subversion, to check out the sources from our repository (available from <http://subversion.tigris.org/>).
- Apache Ant version 1.6 or newer (available from <http://ant.apache.org/>).
- JDK-1.4.2 or later. Although MySQL Connector/J can be installed on older JDKs, to compile it from source you must have at least JDK-1.4.2.

The Subversion source code repository for MySQL Connector/J is located at <http://svn.mysql.com/svnpublic/connector-j>. In general, you should not check out the entire repository because it contains every branch and tag for MySQL Connector/J and is quite large.

To check out and compile a specific branch of MySQL Connector/J, follow these steps:

1. Check out the latest code from the branch that you want with the following command (replacing *[major]* and *[minor]* with appropriate version numbers):

```
shell> svn co »
http://svn.mysql.com/svnpublic/connector-j/branches/branch_[major]_[minor]/connector-j
```

This creates a `connector-j` subdirectory in the current directory that contains the latest sources for the requested branch.

2. Change location to the `connector-j` directory to make it your current working directory:

```
shell> cd connector-j
```

3. Issue the following command to compile the driver and create a `.jar` file suitable for installation:

```
shell> ant dist
```

This creates a `build` directory in the current directory, where all build output will go. A directory is created in the `build` directory that includes the version number of the sources you are building from. This directory contains the sources, compiled `.class` files, and a `.jar` file suitable for deployment. For other possible targets, including ones that will create a fully packaged distribution, issue the following command:

```
shell> ant -projecthelp
```

4. A newly created `.jar` file containing the JDBC driver will be placed in the directory `build/mysql-connector-java-[version]`.

Install the newly created JDBC driver as you would a binary `.jar` file that you download from MySQL by following the in-

structions in [Section 29.4.2.2, “Installing the Driver and Configuring the CLASSPATH”](#).

If you want to build the Connector/J 5.1 branch then you must have a compatible JDK 6.0 installed.

### 29.4.3. Connector/J Examples

Examples of using Connector/J are located throughout this document, this section provides a summary and links to these examples.

- [Example 29.1, “Obtaining a connection from the DriverManager”](#)
- [Example 29.2, “Using java.sql.Statement to execute a SELECT query”](#)
- [Example 29.3, “Stored Procedures”](#)
- [Example 29.4, “Using Connection.prepareStatement\(\)”](#)
- [Example 29.5, “Registering output parameters”](#)
- [Example 29.6, “Setting CallableStatement input parameters”](#)
- [Example 29.7, “Retrieving results and output parameter values”](#)
- [Example 29.8, “Retrieving AUTO\\_INCREMENT column values using Statement.getGeneratedKeys\(\)”](#)
- [Example 29.9, “Retrieving AUTO\\_INCREMENT column values using SELECT LAST\\_INSERT\\_ID\(\)”](#)
- [Example 29.10, “Retrieving AUTO\\_INCREMENT column values in Updatable ResultSets”](#)
- [Example 29.11, “Using a connection pool with a J2EE application server”](#)
- [Example 29.12, “Example of transaction with retry logic”](#)

### 29.4.4. Connector/J (JDBC) Reference

This section of the manual contains reference material for MySQL Connector/J, some of which is automatically generated during the Connector/J build process.

#### 29.4.4.1. Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J

The name of the class that implements `java.sql.Driver` in MySQL Connector/J is `com.mysql.jdbc.Driver`. The `org.gjt.mm.mysql.Driver` class name is also usable to remain backward-compatible with MM.MySQL. You should use this class name when registering the driver, or when otherwise configuring software to use MySQL Connector/J.

The JDBC URL format for MySQL Connector/J is as follows, with items in square brackets ([, ]) being optional:

```
jdbc:mysql://[host][, failoverhost...][:port]/[database] »
[?propertyName1=value1][&propertyName2=value2]...
```

If the hostname is not specified, it defaults to 127.0.0.1. If the port is not specified, it defaults to 3306, the default port number for MySQL servers.

```
jdbc:mysql://[host:port],[host:port].../[database] »
[?propertyName1=value1][&propertyName2=value2]...
```

If the database is not specified, the connection will be made with no default database. In this case, you will need to either call the `setCatalog()` method on the `Connection` instance or fully-specify table names using the database name (i.e. `SELECT dbname.tablename.colname FROM dbname.tablename...`) in your SQL. Not specifying the database to use upon connection is generally only useful when building tools that work with multiple databases, such as GUI database managers.

MySQL Connector/J has fail-over support. This allows the driver to fail-over to any number of slave hosts and still perform read-only queries. Fail-over only happens when the connection is in an `autoCommit(true)` state, because fail-over can not happen reliably when a transaction is in progress. Most application servers and connection pools set `autoCommit` to `true` at the end of every transaction/connection use.

The fail-over functionality has the following behavior:

- If the URL property `autoReconnect` is `false`: Failover only happens at connection initialization, and fallback occurs when the driver determines that the first host has become available again.
- If the URL property `autoReconnect` is `true`: Failover happens when the driver determines that the connection has failed (before every query), and falls back to the first host when it determines that the host has become available again (after `queriesBeforeRetryMaster` queries have been issued).

In either case, whenever you are connected to a "failed-over" server, the connection will be set to read-only state, so queries that would modify data will have exceptions thrown (the query will **never** be processed by the MySQL server).

Configuration properties define how Connector/J will make a connection to a MySQL server. Unless otherwise noted, properties can be set for a `DataSource` object or for a `Connection` object.

Configuration Properties can be set in one of the following ways:

- Using the `set*()` methods on MySQL implementations of `java.sql.DataSource` (which is the preferred method when using implementations of `java.sql.DataSource`):
  - `com.mysql.jdbc.jdbc2.optional.MysqlDataSource`
  - `com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource`
- As a key/value pair in the `java.util.Properties` instance passed to `DriverManager.getConnection()` or `Driver.connect()`
- As a JDBC URL parameter in the URL given to `java.sql.DriverManager.getConnection()`, `java.sql.Driver.connect()` or the MySQL implementations of the `javax.sql.DataSource` `setURL()` method.

#### Note

If the mechanism you use to configure a JDBC URL is XML-based, you will need to use the XML character literal `&amp;` to separate configuration parameters, as the ampersand is a reserved character for XML.

The properties are listed in the following tables.

#### Connection/Authentication.

| Property Name                                | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Default Value                                     | Since Version |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|---------------|
| <code>user</code>                            | The user to connect as                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                   | all versions  |
| <code>password</code>                        | The password to use when connecting                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                   | all versions  |
| <code>socketFactory</code>                   | The name of the class that the driver should use for creating socket connections to the server. This class must implement the interface <code>'com.mysql.jdbc.SocketFactory'</code> and have public no-args constructor.                                                                                                                                                                                                                                                                                                                                   | <code>com.mysql.jdbc.StandardSocketFactory</code> | 3.0.3         |
| <code>connectTimeout</code>                  | Timeout for socket connect (in milliseconds), with 0 being no timeout. Only works on JDK-1.4 or newer. Defaults to '0'.                                                                                                                                                                                                                                                                                                                                                                                                                                    | 0                                                 | 3.0.1         |
| <code>socketTimeout</code>                   | Timeout on network socket operations (0, the default means no timeout).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 0                                                 | 3.0.1         |
| <code>connectionLifecycleInterceptors</code> | A comma-delimited list of classes that implement <code>"com.mysql.jdbc.ConnectionLifecycleInterceptor"</code> that should notified of connection lifecycle events (creation, destruction, commit, rollback, <code>setCatalog</code> and <code>setAutoCommit</code> ) and potentially alter the execution of these commands. <code>ConnectionLifecycleInterceptors</code> are "stackable", more than one interceptor may be specified via the configuration property as a comma-delimited list, with the interceptors executed in order from left to right. |                                                   | 5.1.4         |
| <code>useConfigs</code>                      | Load the comma-delimited list of configuration properties before parsing the URL or applying user-specified properties. These configurations are explained in the 'Configurations' of the documentation.                                                                                                                                                                                                                                                                                                                                                   |                                                   | 3.1.5         |

|                     |                                                                                                                                                                         |                                |        |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|--------|
| interactiveClient   | Set the CLIENT_INTERACTIVE flag, which tells MySQL to timeout connections based on INTERACTIVE_TIMEOUT instead of WAIT_TIMEOUT                                          | false                          | 3.1.0  |
| localSocketAddress  | Hostname or IP address given to explicitly configure the interface that the driver will bind the client side of the TCP/IP connection to when connecting.               |                                | 5.0.5  |
| mysqlIOFactory      | The name of the class which implements "com.mysql.jdbc.MySQLIO" for communicating with mysqld. (default is "com.mysql.jdbc.MySQLIOprotocol")                            | com.mysql.jdbc.MySQLIOprotocol | 6.0.0  |
| propertiesTransform | An implementation of com.mysql.jdbc.ConnectionPropertiesTransform that the driver will use to modify URL properties passed to the driver before attempting a connection |                                | 3.1.4  |
| useCompression      | Use zlib compression when communicating with the server (true/false)? Defaults to 'false'.                                                                              | false                          | 3.0.17 |

**Networking.**

| Property Name   | Definition                                                                                                                                                                   | Default Value | Since Version |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|---------------|
| tcpKeepAlive    | If connecting using TCP/IP, should the driver set SO_KEEPALIVE?                                                                                                              | true          | 5.0.7         |
| tcpNoDelay      | If connecting using TCP/IP, should the driver set SO_TCP_NODELAY (disabling the Nagle Algorithm)?                                                                            | true          | 5.0.7         |
| tcpRcvBuf       | If connecting using TCP/IP, should the driver set SO_RCV_BUF to the given value? The default value of '0', means use the platform default value for this property)           | 0             | 5.0.7         |
| tcpSndBuf       | If connecting using TCP/IP, should the driver set SO_SND_BUF to the given value? The default value of '0', means use the platform default value for this property)           | 0             | 5.0.7         |
| tcpTrafficClass | If connecting using TCP/IP, should the driver set traffic class or type-of-service fields ?See the documentation for java.net.Socket.setTrafficClass() for more information. | 0             | 5.0.7         |

**High Availability and Clustering.**

| Property Name         | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Default Value | Since Version |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|---------------|
| autoReconnect         | Should the driver try to re-establish stale and/or dead connections? If enabled the driver will throw an exception for a queries issued on a stale or dead connection, which belong to the current transaction, but will attempt reconnect before the next query issued on the connection in a new transaction. The use of this feature is not recommended, because it has side effects related to session state and data consistency when applications don't handle SQLExceptions properly, and is only designed to be used when you are unable to configure your application to handle SQLExceptions resulting from dead and stale connections properly. Alternatively, investigate setting the MySQL server variable "wait_timeout" to some high value rather than the default of 8 hours. | false         | 1.1           |
| autoReconnectForPools | Use a reconnection strategy appropriate for connection pools (defaults to 'false')                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | false         | 3.1.3         |
| failOverReadOnly      | When failing over in autoReconnect mode, should the connection be set to 'read-only'?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | true          | 3.0.12        |
| maxReconnects         | Maximum number of reconnects to attempt if autoReconnect is true, default is '3'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 3             | 1.1           |
| reconnectAtTxEnd      | If autoReconnect is set to true, should the driver attempt reconnects at the end of every transaction?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | false         | 3.0.10        |

|                                   |                                                                                                                                                                                                                                                                                     |       |       |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------|
| initialTimeout                    | If autoReconnect is enabled, the initial time to wait between reconnect attempts (in seconds, defaults to '2').                                                                                                                                                                     | 2     | 1.1   |
| roundRobinLoadBalance             | When autoReconnect is enabled, and failoverReadonly is false, should we pick hosts to connect to on a round-robin basis?                                                                                                                                                            | false | 3.1.2 |
| queriesBeforeRetryMaster          | Number of queries to issue before falling back to master when failed over (when using multi-host failover). Whichever condition is met first, 'queriesBeforeRetryMaster' or 'secondsBeforeRetryMaster' will cause an attempt to be made to reconnect to the master. Defaults to 50. | 50    | 3.0.2 |
| secondsBeforeRetryMaster          | How long should the driver wait, when failed over, before attempting                                                                                                                                                                                                                | 30    | 3.0.2 |
| selfDestructOnPingMaxOperations   | =If set to a non-zero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connection's count of commands sent to the server exceeds this value.                                                | 0     | 5.1.6 |
| selfDestructOnPingSecondsLifetime | If set to a non-zero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connection's lifetime exceeds this value.                                                                             | 0     | 5.1.6 |
| resourceId                        | A globally unique name that identifies the resource that this datasource or connection is connected to, used for XARE-source.isSameRM() when the driver can't determine this value based on hostnames used in the URL                                                               |       | 5.0.1 |

**Security.**

| Property Name                     | Definition                                                                                                                                                                                                                                                              | Default Value | Since Version |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|---------------|
| allowMultiQueries                 | Allow the use of ';' to delimit multiple queries during one statement (true/false), defaults to 'false'                                                                                                                                                                 | false         | 3.1.1         |
| useSSL                            | Use SSL when communicating with the server (true/false), defaults to 'false'                                                                                                                                                                                            | false         | 3.0.2         |
| requireSSL                        | Require SSL connection if useSSL=true? (defaults to 'false').                                                                                                                                                                                                           | false         | 3.1.0         |
| verifyServerCertificate           | If "useSSL" is set to "true", should the driver verify the server's certificate? When using this feature, the keystore parameters should be specified by the "clientCertificateKeyStore*" properties, rather than system properties.                                    | true          | 5.1.6         |
| clientCertificateKeyStoreUrl      | URL to the client certificate KeyStore (if not specified, use defaults)                                                                                                                                                                                                 |               | 5.1.0         |
| clientCertificateKeyStoreType     | KeyStore type for client certificates (NULL or empty means use default, standard keystore types supported by the JVM are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM.       |               | 5.1.0         |
| clientCertificateKeyStorePassword | Password for the client certificates KeyStore                                                                                                                                                                                                                           |               | 5.1.0         |
| trustCertificateKeyStoreUrl       | URL to the trusted root certificate KeyStore (if not specified, use defaults)                                                                                                                                                                                           |               | 5.1.0         |
| trustCertificateKeyStoreType      | KeyStore type for trusted root certificates (NULL or empty means use default, standard keystore types supported by the JVM are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM. |               | 5.1.0         |
| trustCertificateKeyStorePassword  | Password for the trusted root certificates KeyStore                                                                                                                                                                                                                     |               | 5.1.0         |
| allowLoadLocalInfile              | Should the driver allow use of 'LOAD DATA LOCAL INFILE...' (defaults to 'true').                                                                                                                                                                                        | true          | 3.0.3         |
| allowUrlInLocalInfile             | Should the driver allow URLs in 'LOAD DATA LOCAL INFILE' statements?                                                                                                                                                                                                    | false         | 3.1.4         |
| paranoid                          | Take measures to prevent exposure sensitive information in error messages and clear data structures holding sensitive data when possible? (defaults to 'false')                                                                                                         | false         | 3.0.1         |

| Property Name                     | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                              | Default Value | Since Version |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|---------------|
| callableStmtCacheSize             | If 'cacheCallableStmts' is enabled, how many callable statements should be cached?                                                                                                                                                                                                                                                                                                                                                                      | 100           | 3.1.2         |
| metadataCacheSize                 | The number of queries to cache ResultSetMetadata for if cacheResultSetMetadata is set to 'true' (default 50)                                                                                                                                                                                                                                                                                                                                            | 50            | 3.1.1         |
| prepStmtCacheSize                 | If prepared statement caching is enabled, how many prepared statements should be cached?                                                                                                                                                                                                                                                                                                                                                                | 25            | 3.0.10        |
| prepStmtCacheSqlLimit             | If prepared statement caching is enabled, what's the largest SQL the driver will cache the parsing for?                                                                                                                                                                                                                                                                                                                                                 | 256           | 3.0.10        |
| alwaysSendSetIsolation            | Should the driver always communicate with the database when Connection.setTransactionIsolation() is called? If set to false, the driver will only communicate with the database when the requested transaction isolation is different than the whichever is newer, the last value that was set via Connection.setTransactionIsolation(), or the value that was read from the server when the connection was established.                                | true          | 3.1.7         |
| maintainTimeStats                 | Should the driver maintain various internal timers to enable idle time calculations as well as more verbose error messages when the connection to the server fails? Setting this property to false removes at least two calls to System.currentTimeMillis() per query.                                                                                                                                                                                  | true          | 3.1.9         |
| useCursorFetch                    | If connected to MySQL > 5.0.2, and setFetchSize() > 0 on a statement, should that statement use cursor-based fetching to retrieve rows?                                                                                                                                                                                                                                                                                                                 | false         | 5.0.0         |
| blobSendChunkSize                 | Chunk to use when sending BLOB/CLOBs via ServerPreparedStatements                                                                                                                                                                                                                                                                                                                                                                                       | 1048576       | 3.1.9         |
| cacheCallableStmts                | Should the driver cache the parsing stage of CallableStatements                                                                                                                                                                                                                                                                                                                                                                                         | false         | 3.1.2         |
| cachePrepStmts                    | Should the driver cache the parsing stage of PreparedStatements of client-side prepared statements, the "check" for suitability of server-side prepared and server-side prepared statements themselves?                                                                                                                                                                                                                                                 | false         | 3.0.10        |
| cacheResultSetMetadata            | Should the driver cache ResultSetMetadata for Statements and PreparedStatements? (Req. JDK-1.4+, true/false, default 'false')                                                                                                                                                                                                                                                                                                                           | false         | 3.1.1         |
| cacheServerConfiguration          | Should the driver cache the results of 'SHOW VARIABLES' and 'SHOW COLLATION' on a per-URL basis?                                                                                                                                                                                                                                                                                                                                                        | false         | 3.1.5         |
| defaultFetchSize                  | The driver will call setFetchSize(n) with this value on all newly-created Statements                                                                                                                                                                                                                                                                                                                                                                    | 0             | 3.1.9         |
| dontTrackOpenResources            | The JDBC specification requires the driver to automatically track and close resources, however if your application doesn't do a good job of explicitly calling close() on statements or result sets, this can cause memory leakage. Setting this property to true relaxes this constraint, and can be more memory efficient for some applications.                                                                                                      | false         | 3.1.7         |
| dynamicCalendars                  | Should the driver retrieve the default calendar when required, or cache it per connection/session?                                                                                                                                                                                                                                                                                                                                                      | false         | 3.1.5         |
| elideSetAutoCommits               | If using MySQL-4.1 or newer, should the driver only issue 'set autocommit=n' queries when the server's state doesn't match the requested state by Connection.setAutoCommit(boolean)?                                                                                                                                                                                                                                                                    | false         | 3.1.3         |
| enableQueryTimeouts               | When enabled, query timeouts set via Statement.setQueryTimeout() use a shared java.util.Timer instance for scheduling. Even if the timeout doesn't expire before the query is processed, there will be memory used by the TimerTask for the given timeout which won't be reclaimed until the time the timeout would have expired if it hadn't been cancelled by the driver. High-load environments might want to consider disabling this functionality. | true          | 5.0.6         |
| holdResultsOpenOverStatementClose | Should the driver close result sets on Statement.close() as required by the JDBC specification?                                                                                                                                                                                                                                                                                                                                                         | false         | 3.1.7         |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |         |        |

| largeRowSizeThreshold    | What size result set row should the JDBC driver consider "large", and thus use a more memory-efficient way of representing the row internally?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | 2048    | 5.1.1  |
| loadBalanceStrategy      | If using a load-balanced connection to connect to SQL nodes in a MySQL Cluster/NDB configuration (by using the URL prefix "jdbc:mysql:loadbalance://"), which load balancing algorithm should the driver use: (1) "random" - the driver will pick a random host for each request. This tends to work better than round-robin, as the randomness will somewhat account for spreading loads where requests vary in response time, while round-robin can sometimes lead to overloaded nodes if there are variations in response times across the workload. (2) "bestResponseTime" - the driver will route the request to the host that had the best response time for the previous transaction.                                                                                                                                                                          | random  | 5.0.6  |
| locatorFetchBufferSize   | If 'emulateLocators' is configured to 'true', what size buffer should be used when fetching BLOB data for getBinaryInputStream?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 1048576 | 3.2.1  |
| rewriteBatchedStatements | Should the driver use multiqueries (irregardless of the setting of "allowMultiQueries") as well as rewriting of prepared statements for INSERT into multi-value inserts when executeBatch() is called? Notice that this has the potential for SQL injection if using plain java.sql.Statements and your code doesn't sanitize input correctly. Notice that for prepared statements, server-side prepared statements can not currently take advantage of this rewrite option, and that if you don't specify stream lengths when using PreparedStatement.set*Stream(), the driver won't be able to determine the optimum number of parameters per batch and you might receive an error from the driver that the resultant packet is too large. Statement.getGeneratedKeys() for these rewritten statements only works when the entire batch includes INSERT statements. | false   | 3.1.13 |
| useDirectRowUnpack       | Use newer result set row unpacking code that skips a copy from network buffers to a MySQL packet instance and instead reads directly into the result set row data buffers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | true    | 5.1.1  |
| useDynamicCharsetInfo    | Should the driver use a per-connection cache of character set information queried from the server when necessary, or use a built-in static mapping that is more efficient, but isn't aware of custom character sets or character sets implemented after the release of the JDBC driver?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | true    | 5.0.6  |
| useFastDateParsing       | Use internal String->Date/Time/Timestamp conversion routines to avoid excessive object creation?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | true    | 5.0.5  |
| useFastIntParsing        | Use internal String->Integer conversion routines to avoid excessive object creation?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | true    | 3.1.4  |
| useJvmCharsetConverters  | Always use the character encoding routines built into the JVM, rather than using lookup tables for single-byte character sets?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | false   | 5.0.1  |
| useLocalSessionState     | Should the driver refer to the internal values of autocommit and transaction isolation that are set by Connection.setAutoCommit() and Connection.setTransactionIsolation() and transaction state as maintained by the protocol, rather than querying the database or blindly sending commands to the database for commit() or rollback() method calls?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | false   | 3.1.7  |
| useReadAheadInput        | Use newer, optimized non-blocking, buffered input stream when reading from the server?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | true    | 3.1.5  |

**Debugging/Profiling.**

| Property Name     | Definition                                                                                                                                                                | Default Value                     | Since Version |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|---------------|
| logger            | The name of a class that implements "com.mysql.jdbc.log.Log" that will be used to log messages to. (default is "com.mysql.jdbc.log.StandardLogger", which logs to STDERR) | com.mysql.jdbc.log.StandardLogger | 3.1.1         |
| gatherPerfMetrics | Should the driver gather performance metrics, and report them                                                                                                             | false                             | 3.1.2         |

|                                         |                                                                                                                                                                                                |                                                     |        |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|--------|
|                                         | via the configured logger every 'reportMetricsIntervalMillis' milliseconds?                                                                                                                    |                                                     |        |
| profileSQL                              | Trace queries and their execution/fetch times to the configured logger (true/false) defaults to 'false'                                                                                        | false                                               | 3.1.0  |
| profileSql                              | Deprecated, use 'profileSQL' instead. Trace queries and their execution/fetch times on STDERR (true/false) defaults to 'false'                                                                 |                                                     | 2.0.14 |
| reportMetricsIntervalMillis             | If 'gatherPerfMetrics' is enabled, how often should they be logged (in ms)?                                                                                                                    | 30000                                               | 3.1.2  |
| maxQuerySizeToLog                       | Controls the maximum length/size of a query that will get logged when profiling or tracing                                                                                                     | 2048                                                | 3.1.3  |
| packetDebugBufferSize                   | The maximum number of packets to retain when 'enablePacketDebug' is true                                                                                                                       | 20                                                  | 3.1.3  |
| slowQueryThresholdMillis                | If 'logSlowQueries' is enabled, how long should a query (in ms) before it is logged as 'slow'?                                                                                                 | 2000                                                | 3.1.2  |
| slowQueryThresholdNanos                 | If 'useNanosForElapsedTime' is set to true, and this property is set to a non-zero value, the driver will use this threshold (in nanosecond units) to determine if a query was slow.           | 0                                                   | 5.0.7  |
| useUsageAdvisor                         | Should the driver issue 'usage' warnings advising proper and efficient usage of JDBC and MySQL Connector/J to the log (true/false, defaults to 'false')?                                       | false                                               | 3.1.1  |
| autoGenerateTestcaseScript              | Should the driver dump the SQL it is executing, including server-side prepared statements to STDERR?                                                                                           | false                                               | 3.1.9  |
| autoSlowLog                             | Instead of using slowQueryThreshold* to determine if a query is slow enough to be logged, maintain statistics that allow the driver to determine queries that are outside the 99th percentile? | true                                                | 5.1.4  |
| clientInfoProvider                      | The name of a class that implements the com.mysql.jdbc.JDBC4ClientInfoProvider interface in order to support JDBC-4.0's Connection.getClientInfo() methods                                     | com.mysql.jdbc.JDBC4ClientInfoProvider              | 5.1.0  |
| dumpMetadataOnColumnNotFound            | Should the driver dump the field-level metadata of a result set into the exception message when ResultSet.findColumn() fails?                                                                  | false                                               | 3.1.13 |
| dumpQueriesOnException                  | Should the driver dump the contents of the query sent to the server in the message for SQLExceptions?                                                                                          | false                                               | 3.1.3  |
| enablePacketDebug                       | When enabled, a ring-buffer of 'packetDebugBufferSize' packets will be kept, and dumped when exceptions are thrown in key areas in the driver's code                                           | false                                               | 3.1.3  |
| explainSlowQueries                      | If 'logSlowQueries' is enabled, should the driver automatically issue an 'EXPLAIN' on the server and send the results to the configured log at a WARN level?                                   | false                                               | 3.1.2  |
| includeInnodbStatusInDeadlockExceptions | Include the output of "SHOW ENGINE INNODB STATUS" in exception messages when deadlock exceptions are detected?                                                                                 | false                                               | 5.0.7  |
| logSlowQueries                          | Should queries that take longer than 'slowQueryThresholdMillis' be logged?                                                                                                                     | false                                               | 3.1.2  |
| logXaCommands                           | Should the driver log XA commands sent by MySQLXaConnection to the server, at the DEBUG level of logging?                                                                                      | false                                               | 5.0.5  |
| profilerEventHandler                    | Name of a class that implements the interface com.mysql.jdbc.profiler.ProfilerEventHandler that will be used to handle profiling/tracing events.                                               | com.mysql.jdbc.profiler.LoggingProfilerEventHandler | 5.1.6  |
| resultSetSizeThreshold                  | If the usage advisor is enabled, how many rows should a result set contain before the driver warns that it is suspiciously large?                                                              | 100                                                 | 5.0.5  |
| traceProtocol                           | Should trace-level network protocol be logged?                                                                                                                                                 | false                                               | 3.1.2  |
| useNanosForElapsedTime                  | For profiling/debugging functionality that measures elapsed time, should the driver try to use nanoseconds resolution if                                                                       | false                                               | 5.0.7  |

**Miscellaneous.**

| Property Name                           | Definition                                                                                                                                                                                                                                                                                                        | Default Value | Since Version |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|---------------|
| useUnicode                              | Should the driver use Unicode character encodings when handling strings? Should only be used when the driver can't determine the character set mapping, or you are trying to 'force' the driver to use a character set that MySQL either doesn't natively support (such as UTF-8), true/false, defaults to 'true' | true          | 1.1g          |
| characterEncoding                       | If 'useUnicode' is set to true, what character encoding should the driver use when dealing with strings? (defaults is to 'autodetect')                                                                                                                                                                            |               | 1.1g          |
| characterSetResults                     | Character set to tell the server to return results as.                                                                                                                                                                                                                                                            |               | 3.0.13        |
| connectionCollation                     | If set, tells the server to use this collation via 'set collation_connection'                                                                                                                                                                                                                                     |               | 3.0.13        |
| useBlobToStoreUTF8OutsideBMP            | Tells the driver to treat [MEDIUM/LONG]BLOB columns as [LONG]VARCHAR columns holding text encoded in UTF-8 that has characters outside the BMP (4-byte encodings), which MySQL server can't handle natively.                                                                                                      | false         | 5.1.3         |
| utf8OutsideBmpExcludedColumnNamePattern | When "useBlobToStoreUTF8OutsideBMP" is set to "true", column names matching the given regex will still be treated as BLOBs unless they match the regex specified for "utf8OutsideBmpIncludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package.                          |               | 5.1.3         |
| utf8OutsideBmpIncludedColumnNamePattern | Used to specify exclusion rules to "utf8OutsideBmpExcludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package.                                                                                                                                                            |               | 5.1.3         |
| sessionVariables                        | A comma-separated list of name/value pairs to be sent as SET SESSION ... to the server when the driver connects.                                                                                                                                                                                                  |               | 3.1.8         |
| allowNaNAndInf                          | Should the driver allow NaN or +/- INF values in PreparedStatement.setDouble()?                                                                                                                                                                                                                                   | false         | 3.1.5         |
| autoClosePstmtStreams                   | Should the driver automatically call .close() on streams/readers passed as arguments via set*() methods?                                                                                                                                                                                                          | false         | 3.1.12        |
| autoDeserialize                         | Should the driver automatically detect and de-serialize objects stored in BLOB fields?                                                                                                                                                                                                                            | false         | 3.1.5         |
| blobsAreStrings                         | Should the driver always treat BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses?                                                                                                                                                                       | false         | 5.0.8         |
| capitalizeTypeNames                     | Capitalize type names in DatabaseMetaData? (usually only useful when using WebObjects, true/false, defaults to 'false')                                                                                                                                                                                           | true          | 2.0.7         |
| clobCharacterEncoding                   | The character encoding to use for sending and retrieving TEXT, MEDIUMTEXT and LONGTEXT values instead of the configured connection characterEncoding                                                                                                                                                              |               | 5.0.0         |
| clobberStreamingResults                 | This will cause a 'streaming' ResultSet to be automatically closed, and any outstanding data still streaming from the server to be discarded if another query is executed before all the data has been read from the server.                                                                                      | false         | 3.0.9         |
| continueBatchOnError                    | Should the driver continue processing batch commands if one statement fails. The JDBC spec allows either way (defaults to 'true').                                                                                                                                                                                | true          | 3.0.3         |
| createDatabaseIfNotExist                | Creates the database given in the URL if it doesn't yet exist. Assumes the configured user has permissions to create databases.                                                                                                                                                                                   | false         | 3.1.9         |
| emptyStringsConvertToZero               | Should the driver allow conversions from empty string fields to numeric values of '0'?                                                                                                                                                                                                                            | true          | 3.1.8         |
| emulateLocators                         | Should the driver emulate java.sql.Blobs with locators? With this feature enabled, the driver will delay loading the actual Blob data until the one of the retrieval methods (getInputStream(), getBytes(), and so forth) on the blob data stream has been accessed. For this to work, you must use a             | false         | 3.1.0         |

|                                              |                                                                                                                                                                                                                                                                                                                                                                                                       |       |              |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------------|
|                                              | column alias with the value of the column to the actual name of the Blob. The feature also has the following restrictions: The SELECT that created the result set must reference only one table, the table must have a primary key; the SELECT must alias the original blob column name, specified as a string, to an alternate name; the SELECT must cover all columns that make up the primary key. |       |              |
| emulateUnsupportedPstmts                     | Should the driver detect prepared statements that are not supported by the server, and replace them with client-side emulated versions?                                                                                                                                                                                                                                                               | true  | 3.1.7        |
| functionsNeverReturnBlobs                    | Should the driver always treat data from functions returning BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses?                                                                                                                                                                                                                             | false | 5.0.8        |
| generateSimpleParameterMetadata              | Should the driver generate simplified parameter metadata for PreparedStatements when no metadata is available either because the server couldn't support preparing the statement, or server-side prepared statements are disabled?                                                                                                                                                                    | false | 5.0.5        |
| ignoreNonTxTables                            | Ignore non-transactional table warning for rollback? (defaults to 'false').                                                                                                                                                                                                                                                                                                                           | false | 3.0.9        |
| jdbcCompliantTruncation                      | Should the driver throw java.sql.DataTruncation exceptions when data is truncated as is required by the JDBC specification when connected to a server that supports warnings (MySQL 4.1.0 and newer)? This property has no effect if the server sql-mode includes STRICT_TRANS_TABLES.                                                                                                                | true  | 3.1.2        |
| maxRows                                      | The maximum number of rows to return (0, the default means return all rows).                                                                                                                                                                                                                                                                                                                          | -1    | all versions |
| netTimeoutForStreamingResults                | What value should the driver automatically set the server setting 'net_write_timeout' to when the streaming result sets feature is in use? (value has unit of seconds, the value '0' means the driver will not try and adjust this value)                                                                                                                                                             | 600   | 5.1.0        |
| noAccessToProcedureBodies                    | When determining procedure parameter types for CallableStatements, and the connected user can't access procedure bodies through "SHOW CREATE PROCEDURE" or select on mysql.proc should the driver instead create basic metadata (all parameters reported as IN VARCHARs, but allowing registerOutParameter() to be called on them anyway) instead of throwing an exception?                           | false | 5.0.3        |
| noDatetimeStringSync                         | Don't ensure that ResultSet.getDatetimeType().toString().equals(ResultSet.getString())                                                                                                                                                                                                                                                                                                                | false | 3.1.7        |
| noTimezoneConversionForTimeType              | Don't convert TIME values using the server timezone if 'use-Timezone='true'                                                                                                                                                                                                                                                                                                                           | false | 5.0.0        |
| nullCatalogMeansCurrent                      | When DatabaseMetadataMethods ask for a 'catalog' parameter, does the value null mean use the current catalog? (this is not JDBC-compliant, but follows legacy behavior from earlier versions of the driver)                                                                                                                                                                                           | true  | 3.1.8        |
| nullNamePatternMatchesAll                    | Should DatabaseMetaMethods that accept *pattern parameters treat null the same as '%' (this is not JDBC-compliant, however older versions of the driver accepted this departure from the specification)                                                                                                                                                                                               | true  | 3.1.8        |
| overrideSupportsIntegrityEnhancementFacility | Should the driver return "true" for DatabaseMetaMethods.supportsIntegrityEnhancementFacility() even if the database doesn't support it to workaround applications that require this method to return "true" to signal support of foreign keys, even though the SQL specification states that this facility contains much more than just foreign key support (one such application being OpenOffice)?  | false | 3.1.12       |
| padCharsWithSpace                            | If a result set column has the CHAR type and the value does not fill the amount of characters specified in the DDL for the column, should the driver pad the remaining characters with space (for ANSI compliance)?                                                                                                                                                                                   | false | 5.0.6        |
| pedantic                                     | Follow the JDBC spec to the letter.                                                                                                                                                                                                                                                                                                                                                                   | false | 3.0.0        |
| pinGlobalTxToPhysicalConnection              | When using XAConnections, should the driver ensure that oper-                                                                                                                                                                                                                                                                                                                                         | false | 5.0.1        |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |       |        |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|--------|
|                                    | ations on a given XID are always routed to the same physical connection? This allows the XAConnection to support "XA START ... JOIN" after "XA END" has been called                                                                                                                                                                                                                                                                                                                                                             |       |        |
| populateInsertRowWithDefaultValues | When using ResultSets that are CONCUR_UPDATABLE, should the driver pre-populate the "insert" row with default values from the DDL for the table used in the query so those values are immediately available for ResultSet accessors? This functionality requires a call to the database for metadata each time a result set of this type is created. If disabled (the default), the default values will be populated by the an internal call to refreshRow() which pulls back default values and/or values changed by triggers. | false | 5.0.5  |
| processEscapeCodesForPrepStmts     | Should the driver process escape codes in queries that are prepared?                                                                                                                                                                                                                                                                                                                                                                                                                                                            | true  | 3.1.12 |
| relaxAutoCommit                    | If the version of MySQL the driver connects to does not support transactions, still allow calls to commit(), rollback() and setAutoCommit() (true/false, defaults to 'false')?                                                                                                                                                                                                                                                                                                                                                  | false | 2.0.13 |
| retainStatementAfterResultSetClose | Should the driver retain the Statement reference in a ResultSet after ResultSet.close() has been called. This is not JDBC-compliant after JDBC-4.0.                                                                                                                                                                                                                                                                                                                                                                             | false | 3.1.11 |
| rollbackOnPooledClose              | Should the driver issue a rollback() when the logical connection in a pool is closed?                                                                                                                                                                                                                                                                                                                                                                                                                                           | true  | 3.0.15 |
| runningCTS13                       | Enables workarounds for bugs in Sun's JDBC compliance test-suite version 1.3                                                                                                                                                                                                                                                                                                                                                                                                                                                    | false | 3.1.7  |
| serverTimezone                     | Override detection/mapping of timezone. Used when timezone from server doesn't map to Java timezone                                                                                                                                                                                                                                                                                                                                                                                                                             |       | 3.0.2  |
| statementInterceptors              | A comma-delimited list of classes that implement "com.mysql.jdbc.StatementInterceptor" that should be placed "in between" query execution to influence the results. StatementInterceptors are "chainable", the results returned by the "current" interceptor will be passed on to the next in the chain, from left-to-right order, as specified in this property.                                                                                                                                                               |       | 5.1.1  |
| strictFloatingPoint                | Used only in older versions of compliance test                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | false | 3.0.0  |
| strictUpdates                      | Should the driver do strict checking (all primary keys selected) of updatable result sets (true, false, defaults to 'true')?                                                                                                                                                                                                                                                                                                                                                                                                    | true  | 3.0.4  |
| tinyInt1isBit                      | Should the driver treat the datatype TINYINT(1) as the BIT type (because the server silently converts BIT -> TINYINT(1) when creating tables)?                                                                                                                                                                                                                                                                                                                                                                                  | true  | 3.0.16 |
| transformedBitsIsBoolean           | If the driver converts TINYINT(1) to a different type, should it use BOOLEAN instead of BIT for future compatibility with MySQL-5.0, as MySQL-5.0 has a BIT type?                                                                                                                                                                                                                                                                                                                                                               | false | 3.1.9  |
| treatUtilDateAsTimestamp           | Should the driver treat java.util.Date as a TIMESTAMP for the purposes of PreparedStatement.setObject()?                                                                                                                                                                                                                                                                                                                                                                                                                        | true  | 5.0.5  |
| ultraDevHack                       | Create PreparedStatements for prepareCall() when required, because UltraDev is broken and issues a prepareCall() for _all_ statements? (true/false, defaults to 'false')                                                                                                                                                                                                                                                                                                                                                        | false | 2.0.3  |
| useGmtMillisForDatetimes           | Convert between session timezone and GMT before creating Date and Timestamp instances (value of "false" is legacy behavior, "true" leads to more JDBC-compliant behavior.                                                                                                                                                                                                                                                                                                                                                       | false | 3.1.12 |
| useHostsInPrivileges               | Add '@hostname' to users in DatabaseMetaData.getColumn/TablePrivileges() (true/false), defaults to 'true'.                                                                                                                                                                                                                                                                                                                                                                                                                      | true  | 3.0.2  |
| useInformationSchema               | When connected to MySQL-5.0.7 or newer, should the driver use the INFORMATION_SCHEMA to derive information used by DatabaseMetaData?                                                                                                                                                                                                                                                                                                                                                                                            | false | 5.0.0  |
| useJDBCCompliantTimezoneShift      | Should the driver use JDBC-compliant rules when converting TIME/TIMESTAMP/DATETIME values' timezone information for those JDBC arguments which take a java.util.Calendar argument? (Notice that this option is exclusive of the "use-Timezone=true" configuration option.)                                                                                                                                                                                                                                                      | false | 5.0.0  |
| useLegacyDatetimeCode              | Use code for DATE/TIME/DATETIME/TIMESTAMP hand-                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | true  | 5.1.6  |

|                                |                                                                                                                                                                                                                                                                                          |           |        |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|--------|
|                                | ling in result sets and statements that consistently handles timezone conversions from client to server and back again, or use the legacy code for these datatypes that has been in the driver for backwards-compatibility?                                                              |           |        |
| useOldAliasMetadataBehavior    | Should the driver use the legacy behavior for "AS" clauses on columns and tables, and only return aliases (if any) for ResultSetMetaData.getColumnNames() or ResultSetMetaData.getTableNames() rather than the original column/table name? In 5.0.x, the default value was true.         | false     | 5.0.4  |
| useOldUTF8Behavior             | Use the UTF-8 behavior the driver did when communicating with 4.0 and older servers                                                                                                                                                                                                      | false     | 3.1.6  |
| useOnlyServerErrorMessages     | Don't prepend 'standard' SQLState error messages to error messages returned by the server.                                                                                                                                                                                               | true      | 3.0.15 |
| useSSPSCompatibleTimezoneShift | If migrating from an environment that was using server-side prepared statements, and the configuration property "useJDBCCompliantTimezoneShift" set to "true", use compatible behavior when not using server-side prepared statements when sending TIMESTAMP values to the MySQL server. | false     | 5.0.5  |
| useServerPrepStmts             | Use server-side prepared statements if the server supports them?                                                                                                                                                                                                                         | false     | 3.1.0  |
| useSqlStateCodes               | Use SQL Standard state codes instead of 'legacy' X/Open/SQL state codes (true/false), default is 'true'                                                                                                                                                                                  | true      | 3.1.3  |
| useStreamLengthsInPrepStmts    | Honor stream length parameter in PreparedStatement/ResultSet.setXXXStream() method calls (true/false, defaults to 'true')?                                                                                                                                                               | true      | 3.0.2  |
| useTimezone                    | Convert time/date types between client and server timezones (true/false, defaults to 'false')?                                                                                                                                                                                           | false     | 3.0.2  |
| useUnbufferedInput             | Don't use BufferedInputStream for reading data from the server                                                                                                                                                                                                                           | true      | 3.0.11 |
| yearIsDateType                 | Should the JDBC driver treat the MySQL type "YEAR" as a java.sql.Date, or as a SHORT?                                                                                                                                                                                                    | true      | 3.1.9  |
| zeroDateTimeBehavior           | What should happen when the driver encounters DATETIME values that are composed entirely of zeroes (used by MySQL to represent invalid dates)? Valid values are "exception", "round" and "convertToNull".                                                                                | exception | 3.1.4  |

Connector/J also supports access to MySQL via named pipes on Windows NT/2000/XP using the NamedPipeSocketFactory as a plugin-socket factory via the socketFactory property. If you don't use a namedPipePath property, the default of '\\.\pipe\MySQL' will be used. If you use the [NamedPipeSocketFactory](#), the hostname and port number values in the JDBC url will be ignored. You can enable this feature using:

```
socketFactory=com.mysql.jdbc.NamedPipeSocketFactory
```

Named pipes only work when connecting to a MySQL server on the same physical machine as the one the JDBC driver is being used on. In simple performance tests, it appears that named pipe access is between 30%-50% faster than the standard TCP/IP access.

You can create your own socket factories by following the example code in [com.mysql.jdbc.NamedPipeSocketFactory](#), or [com.mysql.jdbc.StandardSocketFactory](#).

#### 29.4.4.2. JDBC API Implementation Notes

MySQL Connector/J passes all of the tests in the publicly-available version of Sun's JDBC compliance test suite. However, in many places the JDBC specification is vague about how certain functionality should be implemented, or the specification allows leeway in implementation.

This section gives details on a interface-by-interface level about how certain implementation decisions may affect how you use MySQL Connector/J.

- **Blob**

Starting with Connector/J version 3.1.0, you can emulate Blobs with locators by adding the property 'emulateLocators=true' to your JDBC URL. Using this method, the driver will delay loading the actual Blob data until you retrieve the other data and then use retrieval methods ([getInputStream\(\)](#), [getBytes\(\)](#), and so forth) on the blob data stream.

For this to work, you must use a column alias with the value of the column to the actual name of the Blob, for example:

```
SELECT id, 'data' as blob_data from blobtable
```

For this to work, you must also follow these rules:

- The `SELECT` must also reference only one table, the table must have a primary key.
- The `SELECT` must alias the original blob column name, specified as a string, to an alternate name.
- The `SELECT` must cover all columns that make up the primary key.

The Blob implementation does not allow in-place modification (they are copies, as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, you should use the corresponding `PreparedStatement.setBlob()` or `ResultSet.updateBlob()` (in the case of updatable result sets) methods to save changes back to the database.

#### MySQL Enterprise

MySQL Enterprise subscribers will find more information about type conversion in the Knowledge Base article, [Type Conversions Supported by MySQL Connector/J](http://www.mysql.com/products/enterprise/advisors.html). To subscribe to MySQL Enterprise see <http://www.mysql.com/products/enterprise/advisors.html>.

- **CallableStatement**

Starting with Connector/J 3.1.1, stored procedures are supported when connecting to MySQL version 5.0 or newer via the `CallableStatement` interface. Currently, the `getParameterMetaData()` method of `CallableStatement` is not supported.

- **Clob**

The Clob implementation does not allow in-place modification (they are copies, as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, you should use the `PreparedStatement.setClob()` method to save changes back to the database. The JDBC API does not have a `ResultSet.updateClob()` method.

- **Connection**

Unlike older versions of MM.MySQL the `isClosed()` method does not ping the server to determine if it is alive. In accordance with the JDBC specification, it only returns true if `closed()` has been called on the connection. If you need to determine if the connection is still valid, you should issue a simple query, such as `SELECT 1`. The driver will throw an exception if the connection is no longer valid.

- **DatabaseMetaData**

Foreign Key information (`getImportedKeys()/getExportedKeys()` and `getCrossReference()`) is only available from InnoDB tables. However, the driver uses `SHOW CREATE TABLE` to retrieve this information, so when other storage engines support foreign keys, the driver will transparently support them as well.

- **PreparedStatement**

PreparedStatements are implemented by the driver, as MySQL does not have a prepared statement feature. Because of this, the driver does not implement `getParameterMetaData()` or `getMetaData()` as it would require the driver to have a complete SQL parser in the client.

Starting with version 3.1.0 MySQL Connector/J, server-side prepared statements and binary-encoded result sets are used when the server supports them.

Take care when using a server-side prepared statement with **large** parameters that are set via `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()`, or `setClob()`. If you want to re-execute the statement with any large parameter changed to a non-large parameter, it is necessary to call `clearParameters()` and set all parameters again. The reason for this is as follows:

- During both server-side prepared statements and client-side emulation, large data is exchanged only when `PreparedStatement.execute()` is called.
- Once that has been done, the stream used to read the data on the client side is closed (as per the JDBC spec), and can't be read from again.
- If a parameter changes from large to non-large, the driver must reset the server-side state of the prepared statement to allow

the parameter that is being changed to take the place of the prior large value. This removes all of the large data that has already been sent to the server, thus requiring the data to be re-sent, via the `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()` or `setClob()` methods.

Consequently, if you want to change the type of a parameter to a non-large one, you must call `clearParameters()` and set all parameters of the prepared statement again before it can be re-executed.

- **ResultSet**

By default, ResultSets are completely retrieved and stored in memory. In most cases this is the most efficient way to operate, and due to the design of the MySQL network protocol is easier to implement. If you are working with ResultSets that have a large number of rows or large values, and can not allocate heap space in your JVM for the memory required, you can tell the driver to stream the results back one row at a time.

To enable this functionality, you need to create a Statement instance in the following manner:

```
stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
 java.sql.ResultSet.CONCUR_READ_ONLY);
stmt.setFetchSize(Integer.MIN_VALUE);
```

The combination of a forward-only, read-only result set, with a fetch size of `Integer.MIN_VALUE` serves as a signal to the driver to stream result sets row-by-row. After this any result sets created with the statement will be retrieved row-by-row.

There are some caveats with this approach. You will have to read all of the rows in the result set (or close it) before you can issue any other queries on the connection, or an exception will be thrown.

The earliest the locks these statements hold can be released (whether they be `MyISAM` table-level locks or row-level locks in some other storage engine such as `InnoDB`) is when the statement completes.

If the statement is within scope of a transaction, then locks are released when the transaction completes (which implies that the statement needs to complete first). As with most other databases, statements are not complete until all the results pending on the statement are read or the active result set for the statement is closed.

Therefore, if using streaming results, you should process them as quickly as possible if you want to maintain concurrent access to the tables referenced by the statement producing the result set.

- **ResultSetMetaData**

The `isAutoIncrement()` method only works when using MySQL servers 4.0 and newer.

- **Statement**

When using versions of the JDBC driver earlier than 3.2.1, and connected to server versions earlier than 5.0.3, the `setFetchSize()` method has no effect, other than to toggle result set streaming as described above.

Connector/J 5.0.0 and later include support for both `Statement.cancel()` and `Statement.setQueryTimeout()`. Both require MySQL 5.0.0 or newer server, and require a separate connection to issue the `KILL QUERY` statement. In the case of `setQueryTimeout()`, the implementation creates an additional thread to handle the timeout functionality.

### Note

Failures to cancel the statement for `setQueryTimeout()` may manifest themselves as `RuntimeException` rather than failing silently, as there is currently no way to unblock the thread that is executing the query being cancelled due to timeout expiration and have it throw the exception instead.

MySQL does not support SQL cursors, and the JDBC driver doesn't emulate them, so "setCursorName()" has no effect.

Connector/J 5.1.3 and later include two additional methods:

- `setLocalInfileInputStream()` sets an `InputStream` instance that will be used to send data to the MySQL server for a `LOAD DATA LOCAL INFILE` statement rather than a `FileInputStream` or `URLInputStream` that represents the path given as an argument to the statement.

This stream will be read to completion upon execution of a `LOAD DATA LOCAL INFILE` statement, and will automatically be closed by the driver, so it needs to be reset before each call to `execute*()` that would cause the MySQL server to request data to fulfill the request for `LOAD DATA LOCAL INFILE`.

If this value is set to `NULL`, the driver will revert to using a `FileInputStream` or `URLInputStream` as required.

- `getLocalInfileInputStream()` returns the `InputStream` instance that will be used to send data in response to a

`LOAD DATA LOCAL INFILE` statement.

This method returns `NULL` if no such stream has been set via `setLocalInfileInputStream()`.

### 29.4.4.3. Java, JDBC and MySQL Types

MySQL Connector/J is flexible in the way it handles conversions between MySQL data types and Java data types.

In general, any MySQL data type can be converted to a `java.lang.String`, and any numerical type can be converted to any of the Java numerical types, although round-off, overflow, or loss of precision may occur.

Starting with Connector/J 3.1.0, the JDBC driver will issue warnings or throw `DataTruncation` exceptions as is required by the JDBC specification unless the connection was configured not to do so by using the property `jdbcCompliantTruncation` and setting it to `false`.

The conversions that are always guaranteed to work are listed in the following table:

#### Connection Properties - Miscellaneous.

| These MySQL Data Types                                                                                                                                                                                                                                         | Can always be converted to these Java types                                                                                                                                                           |

#### Note

Round-off, overflow or loss of precision may occur if you choose a Java numeric data type that has less precision or capacity than the MySQL data type you are converting to/from.

The `ResultSet.getObject()` method uses the type conversions between MySQL and Java types, following the JDBC specification where appropriate. The value returned by `ResultSetMetaData.getColumnClassName()` is also shown below. For more information on the `java.sql.Types` classes see [Java 2 Platform Types](#).

#### MySQL Types to Java Types for `ResultSet.getObject()`.

| MySQL Type Name                                          | Return value of <code>getColumnClassName</code> | Returned as Java Class                                                                                                                                                                                |
|----------------------------------------------------------|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>BIT(1)</code> (new in MySQL-5.0)                   | <code>BIT</code>                                | <code>java.lang.Boolean</code>                                                                                                                                                                        |
| <code>BIT(&gt; 1)</code> (new in MySQL-5.0)              | <code>BIT</code>                                | <code>byte[]</code>                                                                                                                                                                                   |

| LOBLOB                      | LOBLOB     | <a href="#">byte[]</a>                                                                                                                                                                                                                                                         |
| LONGTEXT                    | VARCHAR    | <a href="#">java.lang.String</a>                                                                                                                                                                                                                                               |
| ENUM('value1','value2',...) | CHAR       | <a href="#">java.lang.String</a>                                                                                                                                                                                                                                               |
| SET('value1','value2',...)  | CHAR       | <a href="#">java.lang.String</a>                                                                                                                                                                                                                                               |

#### 29.4.4.4. Using Character Sets and Unicode

All strings sent from the JDBC driver to the server are converted automatically from native Java Unicode form to the client character encoding, including all queries sent via [Statement.execute\(\)](#), [Statement.executeUpdate\(\)](#), [Statement.executeQuery\(\)](#) as well as all [PreparedStatement](#) and [CallableStatement](#) parameters with the exclusion of parameters set using [setBytes\(\)](#), [setBinaryStream\(\)](#), [setAsciiStream\(\)](#), [setUnicodeStream\(\)](#) and [setBlob\(\)](#).

Prior to MySQL Server 4.1, Connector/J supported a single character encoding per connection, which could either be automatically detected from the server configuration, or could be configured by the user through the [useUnicode](#) and [characterEncoding](#) properties.

Starting with MySQL Server 4.1, Connector/J supports a single character encoding between client and server, and any number of character encodings for data returned by the server to the client in [ResultSets](#).

The character encoding between client and server is automatically detected upon connection. The encoding used by the driver is specified on the server via the [character\\_set](#) system variable for server versions older than 4.1.0 and [character\\_set\\_server](#) for server versions 4.1.0 and newer. For more information, see [Section 9.1.3.1, “Server Character Set and Collation”](#).

To override the automatically-detected encoding on the client side, use the [characterEncoding](#) property in the URL used to connect to the server.

When specifying character encodings on the client side, Java-style names should be used. The following table lists Java-style names for MySQL character sets:

##### MySQL to Java Encoding Name Translations.

| MySQL Character Set Name | Java-Style Character Encoding Name |
|--------------------------|------------------------------------|
| ascii                    | US-ASCII                           |
| big5                     | Big5                               |
| gbk                      | GBK                                |

|          |                                                    |
|----------|----------------------------------------------------|
| sjis     | SJIS (or Cp932 or MS932 for MySQL Server < 4.1.11) |
| cp932    | Cp932 or MS932 (MySQL Server > 4.1.11)             |
| gb2312   | EUC_CN                                             |
| ujis     | EUC_JP                                             |
| euckr    | EUC_KR                                             |
| latin1   | ISO8859_1                                          |
| latin2   | ISO8859_2                                          |
| greek    | ISO8859_7                                          |
| hebrew   | ISO8859_8                                          |
| cp866    | Cp866                                              |
| tis620   | TIS620                                             |
| cp1250   | Cp1250                                             |
| cp1251   | Cp1251                                             |
| cp1257   | Cp1257                                             |
| macroman | MacRoman                                           |
| macce    | MacCentralEurope                                   |
| utf8     | UTF-8                                              |
| ucs2     | UnicodeBig                                         |

### Warning

Do not issue the query 'set names' with Connector/J, as the driver will not detect that the character set has changed, and will continue to use the character set detected during the initial connection setup.

To allow multiple character sets to be sent from the client, the UTF-8 encoding should be used, either by configuring `utf8` as the default server character set, or by configuring the JDBC driver to use UTF-8 through the `characterEncoding` property.

## 29.4.4.5. Connecting Securely Using SSL

SSL in MySQL Connector/J encrypts all data (other than the initial handshake) between the JDBC driver and the server. The performance penalty for enabling SSL is an increase in query processing time between 35% and 50%, depending on the size of the query, and the amount of data it returns.

For SSL Support to work, you must have the following:

- A JDK that includes JSSE (Java Secure Sockets Extension), like JDK-1.4.1 or newer. SSL does not currently work with a JDK that you can add JSSE to, like JDK-1.2.x or JDK-1.3.x due to the following JSSE bug: <http://developer.java.sun.com/developer/bugParade/bugs/4273544.html>
- A MySQL server that supports SSL and has been compiled and configured to do so, which is MySQL-4.0.4 or later, see [Section 5.5.7, “Using SSL for Secure Connections”](#), for more information.
- A client certificate (covered later in this section)

The system works through two Java truststore files, one file contains the certificate information for the server (`truststore` in the examples below). The other file contains the certificate for the client (`keystore` in the examples below). All Java truststore files are password protected by supplying a suitable password to the `keytool` when you create the files. You need the file names and associated passwords to create an SSL connection.

You will first need to import the MySQL server CA Certificate into a Java truststore. A sample MySQL server CA Certificate is located in the `SSL` subdirectory of the MySQL source distribution. This is what SSL will use to determine if you are communicating with a secure MySQL server. Alternatively, use the CA Certificate that you have generated or been provided with by your SSL provider.

To use Java's `keytool` to create a truststore in the current directory, and import the server's CA certificate (`cacert.pem`), you can do the following (assuming that `keytool` is in your path. The `keytool` should be located in the `bin` subdirectory of your JDK or JRE):

```
shell> keytool -import -alias mysqlServerCACert \
 -file cacert.pem -keystore truststore
```

You will need to enter the password when prompted for the keystore file. Interaction with `keytool` will look like this:

```
Enter keystore password: *****
Owner: EMAILADDRESS=walrus@example.com, CN=Walrus,
O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Issuer: EMAILADDRESS=walrus@example.com, CN=Walrus,
O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Serial number: 0
Valid from:
 Fri Aug 02 16:55:53 CDT 2002 until: Sat Aug 02 16:55:53 CDT 2003
Certificate fingerprints:
 MD5: 61:91:A0:F2:03:07:61:7A:81:38:66:DA:19:C4:8D:AB
 SHA1: 25:77:41:05:D5:AD:99:8C:14:8C:CA:68:9C:2F:B8:89:C3:34:4D:6C
Trust this certificate? [no]: yes
Certificate was added to keystore
```

You then have two options, you can either import the client certificate that matches the CA certificate you just imported, or you can create a new client certificate.

To import an existing certificate, the certificate should be in DER format. You can use `openssl` to convert an existing certificate into the new format. For example:

```
shell> openssl x509 -outform DER -in client-cert.pem -out client.cert
```

You now need to import the converted certificate into your keystore using `keytool`:

```
shell> keytool -import -file client.cert -keystore keystore -alias mysqlClientCertificate
```

To generate your own client certificate, use `keytool` to create a suitable certificate and add it to the `keystore` file:

```
shell> keytool -genkey -keyalg rsa \
 -alias mysqlClientCertificate -keystore keystore
```

Keytool will prompt you for the following information, and create a keystore named `keystore` in the current directory.

You should respond with information that is appropriate for your situation:

```
Enter keystore password: *****
What is your first and last name?
 [Unknown]: Matthews
What is the name of your organizational unit?
 [Unknown]: Software Development
What is the name of your organization?
 [Unknown]: MySQL AB
What is the name of your City or Locality?
 [Unknown]: Flossmoor
What is the name of your State or Province?
 [Unknown]: IL
What is the two-letter country code for this unit?
 [Unknown]: US
Is <CN=Matthews, OU=Software Development, O=MySQL AB,
L=Flossmoor, ST=IL, C=US> correct?
 [no]: y
Enter key password for <mysqlClientCertificate>
 (RETURN if same as keystore password):
```

Finally, to get JSSE to use the keystore and truststore that you have generated, you need to set the following system properties when you start your JVM, replacing `path_to_keystore_file` with the full path to the keystore file you created, `path_to_truststore_file` with the path to the truststore file you created, and using the appropriate password values for each property. You can do this either on the command line:

```
-Djavax.net.ssl.keyStore=path_to_keystore_file
-Djavax.net.ssl.keyStorePassword=password
-Djavax.net.ssl.trustStore=path_to_truststore_file
-Djavax.net.ssl.trustStorePassword=password
```

Or you can set the values directly within the application:

```
System.setProperty("javax.net.ssl.keyStore", "path_to_keystore_file");
System.setProperty("javax.net.ssl.keyStorePassword", "password");
System.setProperty("javax.net.ssl.trustStore", "path_to_truststore_file");
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

You will also need to set `useSSL` to `true` in your connection parameters for MySQL Connector/J, either by adding `useSSL=true` to your URL, or by setting the property `useSSL` to `true` in the `java.util.Properties` instance you pass to `DriverManager.getConnection()`.

You can test that SSL is working by turning on JSSE debugging (as detailed below), and look for the following key events:

```

...

JSSE provides debugging (to STDOUT) when you set the following system property: `-Djavax.net.debug=all` This will tell you what keystores and truststores are being used, as well as what is going on during the SSL handshake and certificate exchange. It will be helpful when trying to determine what is not working when trying to get an SSL connection to happen.

#### 29.4.4.6. Using Master/Slave Replication with ReplicationConnection

Starting with Connector/J 3.1.7, we've made available a variant of the driver that will automatically send queries to a read/write master, or a failover or round-robin loadbalanced set of slaves based on the state of `Connection.getReadOnly()`.

An application signals that it wants a transaction to be read-only by calling `Connection.setReadOnly(true)`, this replication-aware connection will use one of the slave connections, which are load-balanced per-vm using a round-robin scheme (a given connection is sticky to a slave unless that slave is removed from service). If you have a write transaction, or if you have a read that is time-sensitive (remember, replication in MySQL is asynchronous), set the connection to be not read-only, by calling `Connection.setReadOnly(false)` and the driver will ensure that further calls are sent to the master MySQL server. The driver takes care of propagating the current state of autocommit, isolation level, and catalog between all of the connections that it uses to accomplish this load balancing functionality.

To enable this functionality, use the "`com.mysql.jdbc.ReplicationDriver`" class when configuring your application server's connection pool or when creating an instance of a JDBC driver for your standalone application. Because it accepts the same URL format as the standard MySQL JDBC driver, `ReplicationDriver` does not currently work with `java.sql.DriverManager`-based connection creation unless it is the only MySQL JDBC driver registered with the `DriverManager`.

Here is a short, simple example of how `ReplicationDriver` might be used in a standalone application.

```

import java.sql.Connection;
import java.sql.ResultSet;
import java.util.Properties;

import com.mysql.jdbc.ReplicationDriver;

public class ReplicationDriverDemo {

 public static void main(String[] args) throws Exception {
 ReplicationDriver driver = new ReplicationDriver();

 Properties props = new Properties();

 // We want this for failover on the slaves
 props.put("autoReconnect", "true");

 // We want to load balance between the slaves
 props.put("roundRobinLoadBalance", "true");

 props.put("user", "foo");
 props.put("password", "bar");
 }
}

```

```

//
// Looks like a normal MySQL JDBC url, with a
// comma-separated list of hosts, the first
// being the 'master', the rest being any number
// of slaves that the driver will load balance against
//

Connection conn =
 driver.connect("jdbc:mysql://master,slave1,slave2,slave3/test",
 props);

//
// Perform read/write work on the master
// by setting the read-only flag to "false"
//

conn.setReadOnly(false);
conn.setAutoCommit(false);
conn.createStatement().executeUpdate("UPDATE some_table ...");
conn.commit();

//
// Now, do a query from a slave, the driver automatically picks one
// from the list
//

conn.setReadOnly(true);

ResultSet rs =
 conn.createStatement().executeQuery("SELECT a,b FROM alt_table");

}

```

You may also want to investigate the Load Balancing JDBC Pool (lbpool) tool, which provides a wrapper around the standard JDBC driver and allows you to use DB connection pools that includes checks for system failures and uneven load distribution. For more information, see [Load Balancing JDBC Pool \(lbpool\)](#).

#### 29.4.4.7. Mapping MySQL Error Numbers to SQLStates

The table below provides a mapping of the MySQL Error Numbers to [SQL States](#)

**Table 29.1. Mapping of MySQL Error Numbers to SQLStates**

| MySQL Error Number | MySQL Error Name     | Legacy (X/Open) SQLState | SQL Standard SQLState |
|--------------------|----------------------|--------------------------|-----------------------|
| 1022               | ER_DUP_KEY           | S1000                    | 23000                 |
| 1037               | ER_OUT_OFMEMORY      | S1001                    | HY001                 |
| 1038               | ER_OUT_OF_SORTMEMORY | S1001                    | HY001                 |
| 1040               | ER_CON_COUNT_ERROR   | 08004                    | 08004                 |
| 1042               | ER_BAD_HOST_ERROR    | 08004                    | 08S01                 |
| 1043               | ER_HANDSHAKE_ERROR   | 08004                    | 08S01                 |
| 1044               | ER_DBA               | S10                      | 420                   |

| MySQL Error Number | MySQL Error Name          | Legacy (X/Open) SQLState | SQL Standard SQLState |
|--------------------|---------------------------|--------------------------|-----------------------|
| 4                  | ACCESS_DENIED_ERROR       | 00                       | 00                    |

## 29.4.5. Connector/J Notes and Tips

### 29.4.5.1. Basic JDBC Concepts

This section provides some general JDBC background.

#### 29.4.5.1.1. Connecting to MySQL Using the [DriverManager](#) Interface

When you are using JDBC outside of an application server, the [DriverManager](#) class manages the establishment of Connections.

The [DriverManager](#) needs to be told which JDBC drivers it should try to make Connections with. The easiest way to do this is

to use `Class.forName()` on the class that implements the `java.sql.Driver` interface. With MySQL Connector/J, the name of this class is `com.mysql.jdbc.Driver`. With this method, you could use an external configuration file to supply the driver class name and driver parameters to use when connecting to a database.

The following section of Java code shows how you might register MySQL Connector/J from the `main()` method of your application:

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

// Notice, do not import com.mysql.jdbc.*
// or you will have problems!

public class LoadDriver {
 public static void main(String[] args) {
 try {
 // The newInstance() call is a work around for some
 // broken Java implementations

 Class.forName("com.mysql.jdbc.Driver").newInstance();
 } catch (Exception ex) {
 // handle the error
 }
 }
}
```

After the driver has been registered with the `DriverManager`, you can obtain a `Connection` instance that is connected to a particular database by calling `DriverManager.getConnection()`:

### Example 29.1. Obtaining a connection from the `DriverManager`

This example shows how you can obtain a `Connection` instance from the `DriverManager`. There are a few different signatures for the `getConnection()` method. You should see the API documentation that comes with your JDK for more specific information on how to use them.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

...
try {
 Connection conn =
 DriverManager.getConnection("jdbc:mysql://localhost/test?" +
 "user=monty&password=greatsqldb");

 // Do something with the Connection

 ...
} catch (SQLException ex) {
 // handle any errors
 System.out.println("SQLException: " + ex.getMessage());
 System.out.println("SQLState: " + ex.getSQLState());
 System.out.println("VendorError: " + ex.getErrorCode());
}
```

Once a `Connection` is established, it can be used to create `Statement` and `PreparedStatement` objects, as well as retrieve metadata about the database. This is explained in the following sections.

#### 29.4.5.1.2. Using Statements to Execute SQL

`Statement` objects allow you to execute basic SQL queries and retrieve the results through the `ResultSet` class which is described later.

To create a `Statement` instance, you call the `createStatement()` method on the `Connection` object you have retrieved via one of the `DriverManager.getConnection()` or `DataSource.getConnection()` methods described earlier.

Once you have a `Statement` instance, you can execute a `SELECT` query by calling the `executeQuery(String)` method with the SQL you want to use.

To update data in the database, use the `executeUpdate(String SQL)` method. This method returns the number of rows affected by the update statement.

If you don't know ahead of time whether the SQL statement will be a `SELECT` or an `UPDATE/INSERT`, then you can use the `execute(String SQL)` method. This method will return true if the SQL query was a `SELECT`, or false if it was an `UPDATE`, `INSERT`, or `DELETE` statement. If the statement was a `SELECT` query, you can retrieve the results by calling the `getResultSet()` method. If the statement was an `UPDATE`, `INSERT`, or `DELETE` statement, you can retrieve the affected rows count by calling `getUpdateCount()` on the `Statement` instance.

**Example 29.2. Using `java.sql.Statement` to execute a `SELECT` query**

```
// assume that conn is an already created JDBC connection
Statement stmt = null;
ResultSet rs = null;

try {
 stmt = conn.createStatement();
 rs = stmt.executeQuery("SELECT foo FROM bar");

 // or alternatively, if you don't know ahead of time that
 // the query will be a SELECT...

 if (stmt.execute("SELECT foo FROM bar")) {
 rs = stmt.getResultSet();
 }

 // Now do something with the ResultSet
} finally {
 // it is a good idea to release
 // resources in a finally{} block
 // in reverse-order of their creation
 // if they are no-longer needed

 if (rs != null) {
 try {
 rs.close();
 } catch (SQLException sqlEx) { // ignore }

 rs = null;
 }

 if (stmt != null) {
 try {
 stmt.close();
 } catch (SQLException sqlEx) { // ignore }

 stmt = null;
 }
}
}
```

**29.4.5.1.3. Using `CallableStatements` to Execute Stored Procedures**

Starting with MySQL server version 5.0 when used with Connector/J 3.1.1 or newer, the `java.sql.CallableStatement` interface is fully implemented with the exception of the `getParameterMetaData()` method.

For more information on MySQL stored procedures, please refer to <http://dev.mysql.com/doc/mysql/en/stored-procedures.html>.

Connector/J exposes stored procedure functionality through JDBC's `CallableStatement` interface.

**Note**

Current versions of MySQL server do not return enough information for the JDBC driver to provide result set metadata for callable statements. This means that when using `CallableStatement`, `ResultSetMetaData` may return `NULL`.

The following example shows a stored procedure that returns the value of `inOutParam` incremented by 1, and the string passed in via `inputParam` as a `ResultSet`:

**Example 29.3. Stored Procedures**

```
CREATE PROCEDURE demoSp(IN inputParam VARCHAR(255), \
 INOUT inOutParam INT)
BEGIN
 DECLARE z INT;
 SET z = inOutParam + 1;
 SET inOutParam = z;

 SELECT inputParam;

 SELECT CONCAT('zyxw', inputParam);
END
```

To use the `demoSp` procedure with Connector/J, follow these steps:

1. Prepare the callable statement by using `Connection.prepareCall()`.

Notice that you have to use JDBC escape syntax, and that the parentheses surrounding the parameter placeholders are not optional:

#### Example 29.4. Using `Connection.prepareCall()`

```
import java.sql.CallableStatement;
...
//
// Prepare a call to the stored procedure 'demoSp'
// with two parameters
//
// Notice the use of JDBC-escape syntax ({call ...})
//
CallableStatement cStmt = conn.prepareCall("{call demoSp(?, ?)}");

cStmt.setString(1, "abcdefg");
```

#### Note

`Connection.prepareCall()` is an expensive method, due to the metadata retrieval that the driver performs to support output parameters. For performance reasons, you should try to minimize unnecessary calls to `Connection.prepareCall()` by reusing `CallableStatement` instances in your code.

2. Register the output parameters (if any exist)

To retrieve the values of output parameters (parameters specified as `OUT` or `INOUT` when you created the stored procedure), JDBC requires that they be specified before statement execution using the various `registerOutputParameter()` methods in the `CallableStatement` interface:

#### Example 29.5. Registering output parameters

```
import java.sql.Types;
...
//
// Connector/J supports both named and indexed
// output parameters. You can register output
// parameters using either method, as well
// as retrieve output parameters using either
// method, regardless of what method was
// used to register them.
//
// The following examples show how to use
// the various methods of registering
// output parameters (you should of course
// use only one registration per parameter).
//
//
// Registers the second parameter as output, and
// uses the type 'INTEGER' for values returned from
// getObject()
//
cStmt.registerOutParameter(2, Types.INTEGER);

//
// Registers the named parameter 'inOutParam', and
// uses the type 'INTEGER' for values returned from
// getObject()
//
cStmt.registerOutParameter("inOutParam", Types.INTEGER);
...

```

3. Set the input parameters (if any exist)

Input and in/out parameters are set as for `PreparedStatement` objects. However, `CallableStatement` also supports setting parameters by name:

#### Example 29.6. Setting `CallableStatement` input parameters

```

...
//
// Set a parameter by index
//
cStmt.setString(1, "abcdefg");

//
// Alternatively, set a parameter using
// the parameter name
//
cStmt.setString("inputParameter", "abcdefg");

//
// Set the 'in/out' parameter using an index
//
cStmt.setInt(2, 1);

//
// Alternatively, set the 'in/out' parameter
// by name
//
cStmt.setInt("inOutParam", 1);
...

```

4. Execute the `CallableStatement`, and retrieve any result sets or output parameters.

Although `CallableStatement` supports calling any of the `Statement` execute methods (`executeUpdate()`, `executeQuery()` or `execute()`), the most flexible method to call is `execute()`, as you do not need to know ahead of time if the stored procedure returns result sets:

### Example 29.7. Retrieving results and output parameter values

```

...
boolean hadResults = cStmt.execute();

//
// Process all returned result sets
//
while (hadResults) {
 ResultSet rs = cStmt.getResultSet();

 // process result set
 ...

 hadResults = cStmt.getMoreResults();
}

//
// Retrieve output parameters
//
// Connector/J supports both index-based and
// name-based retrieval
//
int outputValue = cStmt.getInt(2); // index-based
outputValue = cStmt.getInt("inOutParam"); // name-based
...

```

#### 29.4.5.1.4. Retrieving `AUTO_INCREMENT` Column Values

Before version 3.0 of the JDBC API, there was no standard way of retrieving key values from databases that supported auto increment or identity columns. With older JDBC drivers for MySQL, you could always use a MySQL-specific method on the `Statement` interface, or issue the query `SELECT LAST_INSERT_ID()` after issuing an `INSERT` to a table that had an `AUTO_INCREMENT` key. Using the MySQL-specific method call isn't portable, and issuing a `SELECT` to get the `AUTO_INCREMENT` key's value requires another round-trip to the database, which isn't as efficient as possible. The following code snippets demonstrate the three different ways to retrieve `AUTO_INCREMENT` values. First, we demonstrate the use of the new JDBC-3.0 method `getGeneratedKeys()` which is now the preferred method to use if you need to retrieve `AUTO_INCREMENT` keys and have access to JDBC-3.0. The second example shows how you can retrieve the same value using a standard `SELECT LAST_INSERT_ID()` query. The final example shows how updatable result sets can retrieve the `AUTO_INCREMENT` value

when using the `insertRow()` method.

### Example 29.8. Retrieving `AUTO_INCREMENT` column values using `Statement.getGeneratedKeys()`

```

Statement stmt = null;
ResultSet rs = null;

try {

 //
 // Create a Statement instance that we can use for
 // 'normal' result sets assuming you have a
 // Connection 'conn' to a MySQL database already
 // available

 stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
 java.sql.ResultSet.CONCUR_UPDATABLE);

 //
 // Issue the DDL queries for the table for this example
 //

 stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
 stmt.executeUpdate(
 "CREATE TABLE autoIncTutorial ("
 + "priKey INT NOT NULL AUTO_INCREMENT, "
 + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

 //
 // Insert one row that will generate an AUTO INCREMENT
 // key in the 'priKey' field
 //

 stmt.executeUpdate(
 "INSERT INTO autoIncTutorial (dataField) "
 + "values ('Can I Get the Auto Increment Field?')",
 Statement.RETURN_GENERATED_KEYS);

 //
 // Example of using Statement.getGeneratedKeys()
 // to retrieve the value of an auto-increment
 // value
 //

 int autoIncKeyFromApi = -1;

 rs = stmt.getGeneratedKeys();

 if (rs.next()) {
 autoIncKeyFromApi = rs.getInt(1);
 } else {
 // throw an exception from here
 }

 rs.close();

 rs = null;

 System.out.println("Key returned from getGeneratedKeys():"
 + autoIncKeyFromApi);
} finally {

 if (rs != null) {
 try {
 rs.close();
 } catch (SQLException ex) {
 // ignore
 }
 }

 if (stmt != null) {
 try {
 stmt.close();
 } catch (SQLException ex) {
 // ignore
 }
 }
}

```

### Example 29.9. Retrieving `AUTO_INCREMENT` column values using `SELECT LAST_INSERT_ID()`

```

Statement stmt = null;
ResultSet rs = null;

try {

 //

```

```

// Create a Statement instance that we can use for
// 'normal' result sets.

stmt = conn.createStatement();

//
// Issue the DDL queries for the table for this example
//

stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
stmt.executeUpdate(
 "CREATE TABLE autoIncTutorial ("
 + "priKey INT NOT NULL AUTO_INCREMENT, "
 + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

//
// Insert one row that will generate an AUTO INCREMENT
// key in the 'priKey' field
//

stmt.executeUpdate(
 "INSERT INTO autoIncTutorial (dataField) "
 + "values ('Can I Get the Auto Increment Field?')");

//
// Use the MySQL LAST_INSERT_ID()
// function to do the same thing as getGeneratedKeys()
//

int autoIncKeyFromFunc = -1;
rs = stmt.executeQuery("SELECT LAST_INSERT_ID()");

if (rs.next()) {
 autoIncKeyFromFunc = rs.getInt(1);
} else {
 // throw an exception from here
}

rs.close();

System.out.println("Key returned from " +
 "SELECT LAST_INSERT_ID(): " +
 autoIncKeyFromFunc);
} finally {

 if (rs != null) {
 try {
 rs.close();
 } catch (SQLException ex) {
 // ignore
 }
 }

 if (stmt != null) {
 try {
 stmt.close();
 } catch (SQLException ex) {
 // ignore
 }
 }
}
}

```

### Example 29.10. Retrieving `AUTO_INCREMENT` column values in `Updatable ResultSets`

```

Statement stmt = null;
ResultSet rs = null;

try {

 //
 // Create a Statement instance that we can use for
 // 'normal' result sets as well as an 'updatable'
 // one, assuming you have a Connection 'conn' to
 // a MySQL database already available
 //

 stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
 java.sql.ResultSet.CONCUR_UPDATABLE);

 //
 // Issue the DDL queries for the table for this example
 //

 stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
 stmt.executeUpdate(
 "CREATE TABLE autoIncTutorial ("
 + "priKey INT NOT NULL AUTO_INCREMENT, "
 + "dataField VARCHAR(64), PRIMARY KEY (priKey))");
}

```

```

//
// Example of retrieving an AUTO INCREMENT key
// from an updatable result set
//
rs = stmt.executeQuery("SELECT priKey, dataField "
 + "FROM autoIncTutorial");

rs.moveToInsertRow();

rs.updateString("dataField", "AUTO INCREMENT here?");
rs.insertRow();

//
// the driver adds rows at the end
//

rs.last();

//
// We should now be on the row we just inserted
//

int autoIncKeyFromRS = rs.getInt("priKey");

rs.close();

rs = null;

System.out.println("Key returned for inserted row: "
 + autoIncKeyFromRS);
} finally {
 if (rs != null) {
 try {
 rs.close();
 } catch (SQLException ex) {
 // ignore
 }
 }

 if (stmt != null) {
 try {
 stmt.close();
 } catch (SQLException ex) {
 // ignore
 }
 }
}
}

```

When you run the preceding example code, you should get the following output: Key returned from `getGeneratedKeys()`: 1 Key returned from `SELECT LAST_INSERT_ID()`: 1 Key returned for inserted row: 2 You should be aware, that at times, it can be tricky to use the `SELECT LAST_INSERT_ID()` query, as that function's value is scoped to a connection. So, if some other query happens on the same connection, the value will be overwritten. On the other hand, the `getGeneratedKeys()` method is scoped by the `Statement` instance, so it can be used even if other queries happen on the same connection, but not on the same `Statement` instance.

## 29.4.5.2. Using Connector/J with J2EE and Other Java Frameworks

This section describes how to use Connector/J in several contexts.

### 29.4.5.2.1. General J2EE Concepts

This section provides general background on J2EE concepts that pertain to use of Connector/J.

#### 29.4.5.2.1.1. Understanding Connection Pooling

Connection pooling is a technique of creating and managing a pool of connections that are ready for use by any thread that needs them.

This technique of pooling connections is based on the fact that most applications only need a thread to have access to a JDBC connection when they are actively processing a transaction, which usually take only milliseconds to complete. When not processing a transaction, the connection would otherwise sit idle. Instead, connection pooling allows the idle connection to be used by some other thread to do useful work.

In practice, when a thread needs to do work against a MySQL or other database with JDBC, it requests a connection from the pool. When the thread is finished using the connection, it returns it to the pool, so that it may be used by any other threads that want to use it.

When the connection is loaned out from the pool, it is used exclusively by the thread that requested it. From a programming point of view, it is the same as if your thread called `DriverManager.getConnection()` every time it needed a JDBC connection, however with connection pooling, your thread may end up using either a new, or already-existing connection.

Connection pooling can greatly increase the performance of your Java application, while reducing overall resource usage. The main benefits to connection pooling are:

- Reduced connection creation time

Although this is not usually an issue with the quick connection setup that MySQL offers compared to other databases, creating new JDBC connections still incurs networking and JDBC driver overhead that will be avoided if connections are recycled.

- Simplified programming model

When using connection pooling, each individual thread can act as though it has created its own JDBC connection, allowing you to use straight-forward JDBC programming techniques.

- Controlled resource usage

If you don't use connection pooling, and instead create a new connection every time a thread needs one, your application's resource usage can be quite wasteful and lead to unpredictable behavior under load.

Remember that each connection to MySQL has overhead (memory, CPU, context switches, and so forth) on both the client and server side. Every connection limits how many resources there are available to your application as well as the MySQL server. Many of these resources will be used whether or not the connection is actually doing any useful work!

Connection pools can be tuned to maximize performance, while keeping resource utilization below the point where your application will start to fail rather than just run slower.

Luckily, Sun has standardized the concept of connection pooling in JDBC through the JDBC-2.0 Optional interfaces, and all major application servers have implementations of these APIs that work fine with MySQL Connector/J.

Generally, you configure a connection pool in your application server configuration files, and access it via the Java Naming and Directory Interface (JNDI). The following code shows how you might use a connection pool from an application deployed in a J2EE application server:

### Example 29.11. Using a connection pool with a J2EE application server

```
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;

import javax.naming.InitialContext;
import javax.sql.DataSource;

public class MyServletJspOrEjb {

 public void doSomething() throws Exception {
 /*
 * Create a JNDI Initial context to be able to
 * lookup the DataSource
 *
 * In production-level code, this should be cached as
 * an instance or static variable, as it can
 * be quite expensive to create a JNDI context.
 *
 * Note: This code only works when you are using servlets
 * or EJBs in a J2EE application server. If you are
 * using connection pooling in standalone Java code, you
 * will have to create/configure datasources using whatever
 * mechanisms your particular connection pooling library
 * provides.
 */

 InitialContext ctx = new InitialContext();

 /*
 * Lookup the DataSource, which will be backed by a pool
 * that the application server provides. DataSource instances
 * are also a good candidate for caching as an instance
 * variable, as JNDI lookups can be expensive as well.
 */

 DataSource ds =
 (DataSource)ctx.lookup("java:comp/env/jdbc/MySQLDB");

 /*
 * The following code is what would actually be in your

```

```

 * Servlet, JSP or EJB 'service' method...where you need
 * to work with a JDBC connection.
 */

 Connection conn = null;
 Statement stmt = null;

 try {
 conn = ds.getConnection();

 /*
 * Now, use normal JDBC programming to work with
 * MySQL, making sure to close each resource when you're
 * finished with it, which allows the connection pool
 * resources to be recovered as quickly as possible
 */

 stmt = conn.createStatement();
 stmt.execute("SOME SQL QUERY");

 stmt.close();
 stmt = null;

 conn.close();
 conn = null;
 } finally {
 /*
 * close any jdbc instances here that weren't
 * explicitly closed during normal code path, so
 * that we don't 'leak' resources...
 */

 if (stmt != null) {
 try {
 stmt.close();
 } catch (SQLException sqlex) {
 // ignore -- as we can't do anything about it here
 }

 stmt = null;
 }

 if (conn != null) {
 try {
 conn.close();
 } catch (SQLException sqlex) {
 // ignore -- as we can't do anything about it here
 }

 conn = null;
 }
 }
}

```

As shown in the example above, after obtaining the JNDI InitialContext, and looking up the DataSource, the rest of the code should look familiar to anyone who has done JDBC programming in the past.

The most important thing to remember when using connection pooling is to make sure that no matter what happens in your code (exceptions, flow-of-control, and so forth), connections, and anything created by them (such as statements or result sets) are closed, so that they may be re-used, otherwise they will be stranded, which in the best case means that the MySQL server resources they represent (such as buffers, locks, or sockets) may be tied up for some time, or worst case, may be tied up forever.

What's the Best Size for my Connection Pool?

As with all other configuration rules-of-thumb, the answer is: it depends. Although the optimal size depends on anticipated load and average database transaction time, the optimum connection pool size is smaller than you might expect. If you take Sun's Java Petstore blueprint application for example, a connection pool of 15-20 connections can serve a relatively moderate load (600 concurrent users) using MySQL and Tomcat with response times that are acceptable.

To correctly size a connection pool for your application, you should create load test scripts with tools such as Apache JMeter or The Grinder, and load test your application.

An easy way to determine a starting point is to configure your connection pool's maximum number of connections to be unbounded, run a load test, and measure the largest amount of concurrently used connections. You can then work backward from there to determine what values of minimum and maximum pooled connections give the best performance for your particular application.

### 29.4.5.2.2. Using Connector/J with Tomcat

The following instructions are based on the instructions for Tomcat-5.x, available at <http://tomcat.apache.org/tomcat-5.5-doc/jndi-datasource-examples-howto.html> which is current at the time this document was written.

First, install the .jar file that comes with Connector/J in `$(CATALINA_HOME)/common/lib` so that it is available to all applica-

tions installed in the container.

Next, Configure the JNDI DataSource by adding a declaration resource to `$/CATALINA_HOME/conf/server.xml` in the context that defines your web application:

```
<Context>
...
<Resource name="jdbc/MySQLDB"
 auth="Container"
 type="javax.sql.DataSource"/>

<!-- The name you used above, must match _exactly_ here!

 The connection pool will be bound into JNDI with the name
 "java:/comp/env/jdbc/MySQLDB"
-->

<ResourceParams name="jdbc/MySQLDB">
 <parameter>
 <name>factory</name>
 <value>org.apache.commons.dbcp.BasicDataSourceFactory</value>
 </parameter>

 <!-- Don't set this any higher than max_connections on your
 MySQL server, usually this should be a 10 or a few 10's
 of connections, not hundreds or thousands -->

 <parameter>
 <name>maxActive</name>
 <value>10</value>
 </parameter>

 <!-- You don't want to many idle connections hanging around
 if you can avoid it, only enough to soak up a spike in
 the load -->

 <parameter>
 <name>maxIdle</name>
 <value>5</value>
 </parameter>

 <!-- Don't use autoReconnect=true, it's going away eventually
 and it's a crutch for older connection pools that couldn't
 test connections. You need to decide whether your application
 is supposed to deal with SQLExceptions (hint, it should), and
 how much of a performance penalty you're willing to pay
 to ensure 'freshness' of the connection -->

 <parameter>
 <name>validationQuery</name>
 <value>SELECT 1</value>
 </parameter>

 <!-- The most conservative approach is to test connections
 before they're given to your application. For most applications
 this is okay, the query used above is very small and takes
 no real server resources to process, other than the time used
 to traverse the network.

 If you have a high-load application you'll need to rely on
 something else. -->

 <parameter>
 <name>testOnBorrow</name>
 <value>true</value>
 </parameter>

 <!-- Otherwise, or in addition to testOnBorrow, you can test
 while connections are sitting idle -->

 <parameter>
 <name>testWhileIdle</name>
 <value>true</value>
 </parameter>

 <!-- You have to set this value, otherwise even though
 you've asked connections to be tested while idle,
 the idle evictor thread will never run -->

 <parameter>
 <name>timeBetweenEvictionRunsMillis</name>
 <value>10000</value>
 </parameter>

 <!-- Don't allow connections to hang out idle too long,
 never longer than what wait_timeout is set to on the
 server...A few minutes or even fraction of a minute
 is sometimes okay here, it depends on your application
 and how much spikey load it will see -->

 <parameter>
 <name>minEvictableIdleTimeMillis</name>
 <value>60000</value>
 </parameter>
</ResourceParams>
```

```

<!-- Username and password used when connecting to MySQL -->
<parameter>
 <name>username</name>
 <value>someuser</value>
</parameter>

<parameter>
 <name>password</name>
 <value>somepass</value>
</parameter>

<!-- Class name for the Connector/J driver -->

<parameter>
 <name>driverClassName</name>
 <value>com.mysql.jdbc.Driver</value>
</parameter>

<!-- The JDBC connection url for connecting to MySQL, notice
that if you want to pass any other MySQL-specific parameters
you should pass them here in the URL, setting them using the
parameter tags above will have no effect, you will also
need to use & to separate parameter values as the
ampersand is a reserved character in XML -->

<parameter>
 <name>url</name>
 <value>jdbc:mysql://localhost:3306/test</value>
</parameter>

</ResourceParams>
</Context>

```

In general, you should follow the installation instructions that come with your version of Tomcat, as the way you configure data-sources in Tomcat changes from time-to-time, and unfortunately if you use the wrong syntax in your XML file, you will most likely end up with an exception similar to the following:

```

Error: java.sql.SQLException: Cannot load JDBC driver class 'null ' SQL
state: null

```

### 29.4.5.2.3. Using Connector/J with JBoss

These instructions cover JBoss-4.x. To make the JDBC driver classes available to the application server, copy the .jar file that comes with Connector/J to the `lib` directory for your server configuration (which is usually called `default`). Then, in the same configuration directory, in the subdirectory named `deploy`, create a datasource configuration file that ends with `-ds.xml`, which tells JBoss to deploy this file as a JDBC Datasource. The file should have the following contents:

```

<datasources>
 <local-tx-datasource>
 <!-- This connection pool will be bound into JNDI with the name
 "java:/MySQLDB" -->

 <jndi-name>MySQLDB</jndi-name>
 <connection-url>jdbc:mysql://localhost:3306/dbname</connection-url>
 <driver-class>com.mysql.jdbc.Driver</driver-class>
 <user-name>user</user-name>
 <password>pass</password>

 <min-pool-size>5</min-pool-size>

 <!-- Don't set this any higher than max_connections on your
 MySQL server, usually this should be a 10 or a few 10's
 of connections, not hundreds or thousands -->

 <max-pool-size>20</max-pool-size>

 <!-- Don't allow connections to hang out idle too long,
 never longer than what wait_timeout is set to on the
 server...A few minutes is usually okay here,
 it depends on your application
 and how much spikey load it will see -->

 <idle-timeout-minutes>5</idle-timeout-minutes>

 <!-- If you're using Connector/J 3.1.8 or newer, you can use
 our implementation of these to increase the robustness
 of the connection pool. -->

 <exception-sorter-class-name>
 com.mysql.jdbc.integration.jboss.ExtendedMysqlExceptionSorter
 </exception-sorter-class-name>
 <valid-connection-checker-class-name>
 com.mysql.jdbc.integration.jboss.MysqlValidConnectionChecker
 </valid-connection-checker-class-name>

 </local-tx-datasource>
</datasources>

```

### 29.4.5.2.4. Using Connector/J with Spring

The Spring Framework is a Java-based application framework designed for assisting in application design by providing a way to configure components. The technique used by Spring is a well known design pattern called Dependency Injection (see [Inversion of Control Containers and the Dependency Injection pattern](#)). This article will focus on Java-oriented access to MySQL databases with Spring 2.0. For those wondering, there is a .NET port of Spring appropriately named Spring.NET.

Spring is not only a system for configuring components, but also includes support for aspect oriented programming (AOP). This is one of the main benefits and the foundation for Spring's resource and transaction management. Spring also provides utilities for integrating resource management with JDBC and Hibernate.

For the examples in this section the MySQL world sample database will be used. The first task is to set up a MySQL data source through Spring. Components within Spring use the "bean" terminology. For example, to configure a connection to a MySQL server supporting the world sample database you might use:

```
<util:map id="dbProps">
 <entry key="db.driver" value="com.mysql.jdbc.Driver"/>
 <entry key="db.jdbcurl" value="jdbc:mysql://localhost/world"/>
 <entry key="db.username" value="myuser"/>
 <entry key="db.password" value="mypass"/>
</util:map>
```

In the above example we are assigning values to properties that will be used in the configuration. For the datasource configuration:

```
<bean id="dataSource"
 class="org.springframework.jdbc.datasource.DriverManagerDataSource">
 <property name="driverClassName" value="${db.driver}"/>
 <property name="url" value="${db.jdbcurl}"/>
 <property name="username" value="${db.username}"/>
 <property name="password" value="${db.password}"/>
</bean>
```

The placeholders are used to provide values for properties of this bean. This means that you can specify all the properties of the configuration in one place instead of entering the values for each property on each bean. We do, however, need one more bean to pull this all together. The last bean is responsible for actually replacing the placeholders with the property values.

```
<bean
 class="org.springframework.beans.factory.config.PropertyPlaceholderConfigurer">
 <property name="properties" ref="dbProps"/>
</bean>
```

Now that we have our MySQL data source configured and ready to go, we write some Java code to access it. The example below will retrieve three random cities and their corresponding country using the data source we configured with Spring.

```
// Create a new application context. this processes the Spring config
ApplicationContext ctx =
 new ClassPathXmlApplicationContext("exlappContext.xml");
// Retrieve the data source from the application context
DataSource ds = (DataSource) ctx.getBean("dataSource");
// Open a database connection using Spring's DataSourceUtils
Connection c = DataSourceUtils.getConnection(ds);
try {
 // retrieve a list of three random cities
 PreparedStatement ps = c.prepareStatement(
 "select City.Name as 'City', Country.Name as 'Country' " +
 "from City inner join Country on City.CountryCode = Country.Code " +
 "order by rand() limit 3");
 ResultSet rs = ps.executeQuery();
 while(rs.next()) {
 String city = rs.getString("City");
 String country = rs.getString("Country");
 System.out.printf("The city %s is in %s\n", city, country);
 }
} catch (SQLException ex) {
 // something has failed and we print a stack trace to analyse the error
 ex.printStackTrace();
 // ignore failure closing connection
 try { c.close(); } catch (SQLException e) { }
} finally {
 // properly release our connection
 DataSourceUtils.releaseConnection(c, ds);
}
```

This is very similar to normal JDBC access to MySQL with the main difference being that we are using DataSourceUtils instead of the DriverManager to create the connection.

While it may seem like a small difference, the implications are somewhat far reaching. Spring manages this resource in a way sim-

ilar to a container managed data source in a J2EE application server. When a connection is opened, it can be subsequently accessed in other parts of the code if it is synchronized with a transaction. This makes it possible to treat different parts of your application as transactional instead of passing around a database connection.

#### 29.4.5.2.4.1. Using `JdbcTemplate`

Spring makes extensive use of the Template method design pattern (see [Template Method Pattern](#)). Our immediate focus will be on the `JdbcTemplate` and related classes, specifically `NamedParameterJdbcTemplate`. The template classes handle obtaining and releasing a connection for data access when one is needed.

The next example shows how to use `NamedParameterJdbcTemplate` inside of a DAO (Data Access Object) class to retrieve a random city given a country code.

```
public class Ex2JdbcDao {
 /**
 * Data source reference which will be provided by Spring.
 */
 private DataSource dataSource;

 /**
 * Our query to find a random city given a country code. Notice
 * the ":country" parameter towards the end. This is called a
 * named parameter.
 */
 private String queryString = "select Name from City " +
 "where CountryCode = :country order by rand() limit 1";

 /**
 * Retrieve a random city using Spring JDBC access classes.
 */
 public String getRandomCityByCountryCode(String cuntryCode) {
 // A template that allows using queries with named parameters
 NamedParameterJdbcTemplate template =
 new NamedParameterJdbcTemplate(dataSource);
 // A java.util.Map is used to provide values for the parameters
 Map params = new HashMap();
 params.put("country", cuntryCode);
 // We query for an Object and specify what class we are expecting
 return (String)template.queryForObject(queryString, params, String.class);
 }

 /**
 * A JavaBean setter-style method to allow Spring to inject the data source.
 * @param dataSource
 */
 public void setDataSource(DataSource dataSource) {
 this.dataSource = dataSource;
 }
}
```

The focus in the above code is on the `getRandomCityByCountryCode()` method. We pass a country code and use the `NamedParameterJdbcTemplate` to query for a city. The country code is placed in a Map with the key "country", which is the parameter is named in the SQL query.

To access this code, you need to configure it with Spring by providing a reference to the data source.

```
<bean id="dao" class="code.Ex2JdbcDao">
 <property name="dataSource" ref="dataSource"/>
</bean>
```

At this point, we can just grab a reference to the DAO from Spring and call `getRandomCityByCountryCode()`.

```
// Create the application context
ApplicationContext ctx =
 new ClassPathXmlApplicationContext("ex2appContext.xml");
// Obtain a reference to our DAO
Ex2JdbcDao dao = (Ex2JdbcDao) ctx.getBean("dao");

String countryCode = "USA";

// Find a few random cities in the US
for(int i = 0; i < 4; ++i)
 System.out.printf("A random city in %s is %s%n", countryCode,
 dao.getRandomCityByCountryCode(countryCode));
```

This example shows how to use Spring's JDBC classes to completely abstract away the use of traditional JDBC classes including `Connection` and `PreparedStatement`.

#### 29.4.5.2.4.2. Transactional JDBC Access

You might be wondering how we can add transactions into our code if we don't deal directly with the JDBC classes. Spring

provides a transaction management package that not only replaces JDBC transaction management, but also allows declarative transaction management (configuration instead of code).

In order to use transactional database access, we will need to change the storage engine of the tables in the world database. The downloaded script explicitly creates MyISAM tables which do not support transactional semantics. The InnoDB storage engine does support transactions and this is what we will be using. We can change the storage engine with the following statements.

```
ALTER TABLE City ENGINE=InnoDB;
ALTER TABLE Country ENGINE=InnoDB;
ALTER TABLE CountryLanguage ENGINE=InnoDB;
```

A good programming practice emphasized by Spring is separating interfaces and implementations. What this means is that we can create a Java interface and only use the operations on this interface without any internal knowledge of what the actual implementation is. We will let Spring manage the implementation and with this it will manage the transactions for our implementation.

First you create a simple interface:

```
public interface Ex3Dao {
 Integer createCity(String name, String countryCode,
 String district, Integer population);
}
```

This interface contains one method that will create a new city record in the database and return the id of the new record. Next you need to create an implementation of this interface.

```
public class Ex3DaoImpl implements Ex3Dao {
 protected DataSource dataSource;
 protected SqlUpdate updateQuery;
 protected SqlFunction idQuery;

 public Integer createCity(String name, String countryCode,
 String district, Integer population) {
 updateQuery.update(new Object[] { name, countryCode,
 district, population });
 return getLastId();
 }

 protected Integer getLastId() {
 return idQuery.run();
 }
}
```

You can see that we only operate on abstract query objects here and don't deal directly with the JDBC API. Also, this is the complete implementation. All of our transaction management will be dealt with in the configuration. To get the configuration started, we need to create the DAO.

```
<bean id="dao" class="code.Ex3DaoImpl">
 <property name="dataSource" ref="dataSource"/>
 <property name="updateQuery">...</property>
 <property name="idQuery">...</property>
</bean>
```

Now you need to set up the transaction configuration. The first thing you must do is create transaction manager to manage the data source and a specification of what transaction properties are required for for the `dao` methods.

```
<bean id="transactionManager"
 class="org.springframework.jdbc.datasource.DataSourceTransactionManager">
 <property name="dataSource" ref="dataSource"/>
</bean>

<tx:advice id="txAdvice" transaction-manager="transactionManager">
 <tx:attributes>
 <tx:method name="*" />
 </tx:attributes>
</tx:advice>
```

The preceding code creates a transaction manager that handles transactions for the data source provided to it. The `txAdvice` uses this transaction manager and the attributes specify to create a transaction for all methods. Finally you need to apply this advice with an AOP pointcut.

```
<aop:config>
 <aop:pointcut id="daoMethods"
 expression="execution(* code.Ex3Dao.*(..))"/>
 <aop:advisor advice-ref="txAdvice" pointcut-ref="daoMethods"/>
</aop:config>
```

This basically says that all methods called on the `Ex3Dao` interface will be wrapped in a transaction. To make use of this, you only have to retrieve the `dao` from the application context and call a method on the `dao` instance.

```
Ex3Dao dao = (Ex3Dao) ctx.getBean("dao");
Integer id = dao.createCity(name, countryCode, district, pop);
```

We can verify from this that there is no transaction management happening in our Java code and it's all configured with Spring. This is a very powerful notion and regarded as one of the most beneficial features of Spring.

### 29.4.5.2.4.3. Connection Pooling

In many situations, such as web applications, there will be a large number of small database transactions. When this is the case, it usually makes sense to create a pool of database connections available for web requests as needed. Although MySQL does not spawn an extra process when a connection is made, there is still a small amount of overhead to create and set up the connection. Pooling of connections also alleviates problems such as collecting large amounts of sockets in the `TIME_WAIT` state.

Setting up pooling of MySQL connections with Spring is as simple as changing the data source configuration in the application context. There are a number of configurations that we can use. The first example is based on the [Jakarta Commons DBCP library](#). The example below replaces the source configuration that was based on `DriverManagerDataSource` with DBCP's `BasicDataSource`.

```
<bean id="dataSource" destroy-method="close"
 class="org.apache.commons.dbcp.BasicDataSource">
 <property name="driverClassName" value="${db.driver}"/>
 <property name="url" value="${db.jdbcurl}"/>
 <property name="username" value="${db.username}"/>
 <property name="password" value="${db.password}"/>
 <property name="initialSize" value="3"/>
</bean>
```

The configuration of the two solutions is very similar. The difference is that DBCP will pool connections to the database instead of creating a new connection every time one is requested. We have also set a parameter here called `initialSize`. This tells DBCP that we want three connections in the pool when it is created.

Another way to configure connection pooling is to configure a data source in our J2EE application server. Using JBoss as an example, you can set up the MySQL connection pool by creating a file called `mysql-local-ds.xml` and placing it in the server/default/deploy directory in JBoss. Once we have this setup, we can use JNDI to look it up. With Spring, this lookup is very simple. The data source configuration looks like this.

```
<jee:jndi-lookup id="dataSource" jndi-name="java:MySQL_DS"/>
```

## 29.4.5.3. Common Problems and Solutions

There are a few issues that seem to be commonly encountered often by users of MySQL Connector/J. This section deals with their symptoms, and their resolutions.

### Questions

- [30.4.5.3.1](#): When I try to connect to the database with MySQL Connector/J, I get the following exception:

```
SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0
```

What's going on? I can connect just fine with the MySQL command-line client.

- [30.4.5.3.2](#): My application throws an `SQLException 'No Suitable Driver'`. Why is this happening?
- [30.4.5.3.3](#): I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```
SQLException: Cannot connect to MySQL server on host:3306.
Is there a MySQL server running on the machine/port you
are trying to connect to?
```

```
(java.security.AccessControlException)
SQLState: 08S01
VendorError: 0
```

- [30.4.5.3.4](#): I have a servlet/application that works fine for a day, and then stops working overnight
- [30.4.5.3.5](#): I'm trying to use JDBC-2.0 updatable result sets, and I get an exception saying my result set is not updatable.
- [30.4.5.3.6](#): I cannot connect to the MySQL server using Connector/J, and I'm sure the connection parameters are correct.
- [30.4.5.3.7](#): I am trying to connect to my MySQL server within my application, but I get the following error and stack trace:

```

java.net.SocketException
MESSAGE: Software caused connection abort: recv failed

STACKTRACE:

java.net.SocketException: Software caused connection abort: recv failed
at java.net.SocketInputStream.socketRead0(Native Method)

- [30.4.5.3.8](#): My application is deployed through JBoss and I am using transactions to handle the statements on the MySQL database. Under heavy loads I am getting a error and stack trace, but these only occur after a fixed period of heavy activity.
- [30.4.5.3.9](#): When using `gcj` an `java.io.CharConversionException` is raised when working with certain character sequences.
- [30.4.5.3.10](#): Updating a table that contains a primary key that is either `FLOAT` or compound primary key that uses `FLOAT` fails to update the table and raises an exception.

## Questions and Answers

### 30.4.5.3.1: When I try to connect to the database with MySQL Connector/J, I get the following exception:

```

SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0

```

#### What's going on? I can connect just fine with the MySQL command-line client.

MySQL Connector/J must use TCP/IP sockets to connect to MySQL, as Java does not support Unix Domain Sockets. Therefore, when MySQL Connector/J connects to MySQL, the security manager in MySQL server will use its grant tables to determine whether the connection should be allowed.

You must add the necessary security credentials to the MySQL server for this to happen, using the `GRANT` statement to your MySQL Server. See [Section 12.5.1.3, “GRANT Syntax”](#), for more information.

#### Note

Testing your connectivity with the `mysql` command-line client will not work unless you add the `--host` flag, and use something other than `localhost` for the host. The `mysql` command-line client will use Unix domain sockets if you use the special hostname `localhost`. If you are testing connectivity to `localhost`, use `127.0.0.1` as the hostname instead.

#### Warning

Changing privileges and permissions improperly in MySQL can potentially cause your server installation to not have optimal security properties.

### 30.4.5.3.2: My application throws an SQLException 'No Suitable Driver'. Why is this happening?

There are three possible causes for this error:

- The Connector/J driver is not in your `CLASSPATH`, see [Section 29.4.2, “Connector/J Installation”](#).
- The format of your connection URL is incorrect, or you are referencing the wrong JDBC driver.
- When using `DriverManager`, the `jdbc.drivers` system property has not been populated with the location of the Connector/J driver.

### 30.4.5.3.3: I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```

SQLException: Cannot connect to MySQL server on host:3306.
Is there a MySQL server running on the machine/port you
are trying to connect to?

(java.security.AccessControlException)
SQLState: 08S01
VendorError: 0

```

Either you're running an Applet, your MySQL server has been installed with the "--skip-networking" option set, or your MySQL server has a firewall sitting in front of it.

Applets can only make network connections back to the machine that runs the web server that served the .class files for the applet. This means that MySQL must run on the same machine (or you must have some sort of port re-direction) for this to work. This also means that you will not be able to test applets from your local file system, you must always deploy them to a web server.

MySQL Connector/J can only communicate with MySQL using TCP/IP, as Java does not support Unix domain sockets. TCP/IP communication with MySQL might be affected if MySQL was started with the "--skip-networking" flag, or if it is firewalled.

If MySQL has been started with the "--skip-networking" option set (the Debian Linux package of MySQL server does this for example), you need to comment it out in the file /etc/mysql/my.cnf or /etc/my.cnf. Of course your my.cnf file might also exist in the `data` directory of your MySQL server, or anywhere else (depending on how MySQL was compiled for your system). Binaries created by MySQL AB always look in /etc/my.cnf and [datadir]/my.cnf. If your MySQL server has been firewalled, you will need to have the firewall configured to allow TCP/IP connections from the host where your Java code is running to the MySQL server on the port that MySQL is listening to (by default, 3306).

#### 30.4.5.3.4: I have a servlet/application that works fine for a day, and then stops working overnight

MySQL closes connections after 8 hours of inactivity. You either need to use a connection pool that handles stale connections or use the "autoReconnect" parameter (see [Section 29.4.4.1, "Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J"](#)).

Also, you should be catching SQLExceptions in your application and dealing with them, rather than propagating them all the way until your application exits, this is just good programming practice. MySQL Connector/J will set the SQLState (see `java.sql.SQLException.getSQLState()` in your APIDocs) to "08S01" when it encounters network-connectivity issues during the processing of a query. Your application code should then attempt to re-connect to MySQL at this point.

The following (simplistic) example shows what code that can handle these exceptions might look like:

#### Example 29.12. Example of transaction with retry logic

```
public void doBusinessOp() throws SQLException {
 Connection conn = null;
 Statement stmt = null;
 ResultSet rs = null;

 //
 // How many times do you want to retry the transaction
 // (or at least _getting_ a connection)?
 //
 int retryCount = 5;

 boolean transactionCompleted = false;

 do {
 try {
 conn = getConnection(); // assume getting this from a
 // javax.sql.DataSource, or the
 // java.sql.DriverManager

 conn.setAutoCommit(false);

 //
 // Okay, at this point, the 'retry-ability' of the
 // transaction really depends on your application logic,
 // whether or not you're using autocommit (in this case
 // not), and whether you're using transactional storage
 // engines
 //
 // For this example, we'll assume that it's _not_ safe
 // to retry the entire transaction, so we set retry
 // count to 0 at this point
 //
 // If you were using exclusively transaction-safe tables,
 // or your application could recover from a connection going
 // bad in the middle of an operation, then you would not
 // touch 'retryCount' here, and just let the loop repeat
 // until retryCount == 0.
 //
 retryCount = 0;

 stmt = conn.createStatement();

 String query = "SELECT foo FROM bar ORDER BY baz";

 rs = stmt.executeQuery(query);

 while (rs.next()) {
 }

 rs.close();
 }
 }
}
```

```

rs = null;

stmt.close();
stmt = null;

conn.commit();
conn.close();
conn = null;

transactionCompleted = true;
} catch (SQLException sqlEx) {

 //
 // The two SQL states that are 'retry-able' are 08S01
 // for a communications error, and 40001 for deadlock.
 //
 // Only retry if the error was due to a stale connection,
 // communications problem or deadlock
 //
 String sqlState = sqlEx.getSQLState();

 if ("08S01".equals(sqlState) || "40001".equals(sqlState)) {
 retryCount--;
 } else {
 retryCount = 0;
 }
} finally {
 if (rs != null) {
 try {
 rs.close();
 } catch (SQLException sqlEx) {
 // You'd probably want to log this . . .
 }
 }

 if (stmt != null) {
 try {
 stmt.close();
 } catch (SQLException sqlEx) {
 // You'd probably want to log this as well . . .
 }
 }

 if (conn != null) {
 try {
 //
 // If we got here, and conn is not null, the
 // transaction should be rolled back, as not
 // all work has been done

 try {
 conn.rollback();
 } finally {
 conn.close();
 }
 } catch (SQLException sqlEx) {
 //
 // If we got an exception here, something
 // pretty serious is going on, so we better
 // pass it up the stack, rather than just
 // logging it. . .

 throw sqlEx;
 }
 }
}
} while (!transactionCompleted && (retryCount > 0));
}

```

**Note**

Use of the `autoReconnect` option is not recommended because there is no safe method of reconnecting to the MySQL server without risking some corruption of the connection state or database state information. Instead, you should use a connection pool which will enable your application to connect to the MySQL server using an available connection from the pool. The `autoReconnect` facility is deprecated, and may be removed in a future release.

**30.4.5.3.5: I'm trying to use JDBC-2.0 updatable result sets, and I get an exception saying my result set is not updatable.**

Because MySQL does not have row identifiers, MySQL Connector/J can only update result sets that have come from queries on tables that have at least one primary key, the query must select every primary key and the query can only span one table (that is, no joins). This is outlined in the JDBC specification.

Note that this issue only occurs when using updatable result sets, and is caused because Connector/J is unable to guarantee that it can identify the correct rows within the result set to be updated without having a unique reference to each row. There is no requirement to have a unique field on a table if you are using `UPDATE` or `DELETE` statements on a table where you can individually specify the criteria to be matched using a `WHERE` clause.

**30.4.5.3.6: I cannot connect to the MySQL server using Connector/J, and I'm sure the connection parameters are correct.**

Make sure that the `skip-networking` option has not been enabled on your server. Connector/J must be able to communicate with your server over TCP/IP, named sockets are not supported. Also ensure that you are not filtering connections through a Firewall or other network security system. For more information, see [Section B.1.2.2, “Can't connect to \[local\] MySQL server”](#).

**30.4.5.3.7: I am trying to connect to my MySQL server within my application, but I get the following error and stack trace:**

```
java.net.SocketException
MESSAGE: Software caused connection abort: recv failed

STACKTRACE:

java.net.SocketException: Software caused connection abort: recv failed
at java.net.SocketInputStream.socketRead0(Native Method)
at java.net.SocketInputStream.read(Unknown Source)
at com.mysql.jdbc.MysqlIO.readFully(MysqlIO.java:1392)
at com.mysql.jdbc.MysqlIO.readPacket(MysqlIO.java:1414)
at com.mysql.jdbc.MysqlIO.doHandshake(MysqlIO.java:625)
at com.mysql.jdbc.Connection.createNewIO(Connection.java:1926)
at com.mysql.jdbc.Connection.<init>(Connection.java:452)
at com.mysql.jdbc.NonRegisteringDriver.connect(NonRegisteringDriver.java:411)
```

The error probably indicates that you are using an older version of the Connector/J JDBC driver (2.0.14 or 3.0.x) and you are trying to connect to a MySQL server with version 4.1.x or newer. The older drivers are not compatible with 4.1 or newer of MySQL as they do not support the newer authentication mechanisms.

It is likely that the older version of the Connector/J driver exists within your application directory or your `CLASSPATH` includes the older Connector/J package.

**30.4.5.3.8: My application is deployed through JBoss and I am using transactions to handle the statements on the MySQL database. Under heavy loads I am getting an error and stack trace, but these only occur after a fixed period of heavy activity.**

This is a JBoss, not Connector/J, issue and is connected to the use of transactions. Under heavy loads the time taken for transactions to complete can increase, and the error is caused because you have exceeded the predefined timeout.

You can increase the timeout value by setting the `TransactionTimeout` attribute to the `TransactionManagerService` within the `/conf/jboss-service.xml` file (pre-4.0.3) or `/deploy/jta-service.xml` for JBoss 4.0.3 or later. See [TransactionTimeout](#) within the JBoss wiki for more information.

**30.4.5.3.9: When using gcj a java.io.CharConversionException is raised when working with certain character sequences.**

This is a known issue with `gcj` which raises an exception when it reaches an unknown character or one it cannot convert. You should add `useJvmCharsetConverters=true` to your connection string to force character conversion outside of the `gcj` libraries, or try a different JDK.

**30.4.5.3.10: Updating a table that contains a primary key that is either FLOAT or compound primary key that uses FLOAT fails to update the table and raises an exception.**

Connector/J adds conditions to the `WHERE` clause during an `UPDATE` to check the old values of the primary key. If there is no match then Connector/J considers this a failure condition and raises an exception.

The problem is that rounding differences between supplied values and the values stored in the database may mean that the values never match, and hence the update fails. The issue will affect all queries, not just those from Connector/J.

To prevent this issue, use a primary key that does not use `FLOAT`. If you have to use a floating point column in your primary key use `DOUBLE` or `DECIMAL` types in place of `FLOAT`.

## 29.4.6. Connector/J Support

### 29.4.6.1. Connector/J Community Support

MySQL AB provides assistance to the user community by means of its mailing lists. For Connector/J related issues, you can get help from experienced users by using the MySQL and Java mailing list. Archives and subscription information is available online at <http://lists.mysql.com/java>.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.6.1, “MySQL Mailing Lists”](#).

Community support from experienced users is also available through the [JDBC Forum](#). You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.6.2, “MySQL Community Support at the MySQL](#)

[Forums](#)".

## 29.4.6.2. How to Report Connector/J Bugs or Problems

The normal place to report bugs is <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public, and can be browsed and searched by anyone. If you log in to the system, you will also be able to enter new reports.

If you have found a sensitive security bug in MySQL, you can send email to [<security@mysql.com>](mailto:security@mysql.com).

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release.

This section will help you write your report correctly so that you don't waste your time doing things that may not help us much or at all.

If you have a repeatable bug report, please report it to the bugs database at <http://bugs.mysql.com/>. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

To report other problems, you can use one of the MySQL mailing lists.

Remember that it is possible for us to respond to a message containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details don't matter.

A good principle is this: If you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of Connector/J or MySQL used, and (b) not fully describing the platform on which Connector/J is installed (including the JVM version, and the platform type and version number that MySQL itself is installed on).

This is highly relevant information, and in 99 cases out of 100, the bug report is useless without it. Very often we get questions like, "Why doesn't this work for me?" Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has already been fixed in newer MySQL versions.

Sometimes the error is platform-dependent; in such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If at all possible, you should create a repeatable, standalone testcase that doesn't involve any third-party classes.

To streamline this process, we ship a base class for testcases with Connector/J, named `'com.mysql.jdbc.util.BaseBugReport'`. To create a testcase for Connector/J using this class, create your own class that inherits from `com.mysql.jdbc.util.BaseBugReport` and override the methods `setUp()`, `tearDown()` and `runTest()`.

In the `setUp()` method, create code that creates your tables, and populates them with any data needed to demonstrate the bug.

In the `runTest()` method, create code that demonstrates the bug using the tables and data you created in the `setUp` method.

In the `tearDown()` method, drop any tables you created in the `setUp()` method.

In any of the above three methods, you should use one of the variants of the `getConnection()` method to create a JDBC connection to MySQL:

- `getConnection()` - Provides a connection to the JDBC URL specified in `getUrl()`. If a connection already exists, that connection is returned, otherwise a new connection is created.
- `getNewConnection()` - Use this if you need to get a new connection for your bug report (i.e. there's more than one connection involved).
- `getConnection(String url)` - Returns a connection using the given URL.
- `getConnection(String url, Properties props)` - Returns a connection using the given URL and properties.

If you need to use a JDBC URL that is different from `'jdbc:mysql:///test'`, override the method `getUrl()` as well.

Use the `assertTrue(boolean expression)` and `assertTrue(String failureMessage, boolean expression)` methods to create conditions that must be met in your testcase demonstrating the behavior you are expecting (vs. the behavior you are observing, which is why you are most likely filing a bug report).

Finally, create a `main()` method that creates a new instance of your testcase, and calls the `run` method:

```
public static void main(String[] args) throws Exception {
 new MyBugReport().run();
}
```

Once you have finished your testcase, and have verified that it demonstrates the bug you are reporting, upload it with your bug report to <http://bugs.mysql.com/>.

### 29.4.6.3. Connector/J Change History

The Connector/J Change History (Changelog) is located with the main Changelog for MySQL. See [Section C.5, “MySQL Connector/J Change History”](#).

## 29.5. MySQL Connector/MXJ

MySQL Connector/MXJ is a Java Utility package for deploying and managing a MySQL database. Deploying and using MySQL can be as easy as adding an additional parameter to the JDBC connection url, which will result in the database being started when the first connection is made. This makes it easy for Java developers to deploy applications which require a database by reducing installation barriers for their end-users.

MySQL Connector/MXJ makes the MySQL database appear to be a java-based component. It does this by determining what platform the system is running on, selecting the appropriate binary, and launching the executable. It will also optionally deploy an initial database, with any specified parameters.

Included are instructions for use with a JDBC driver and deploying as a JMX MBean to JBoss.

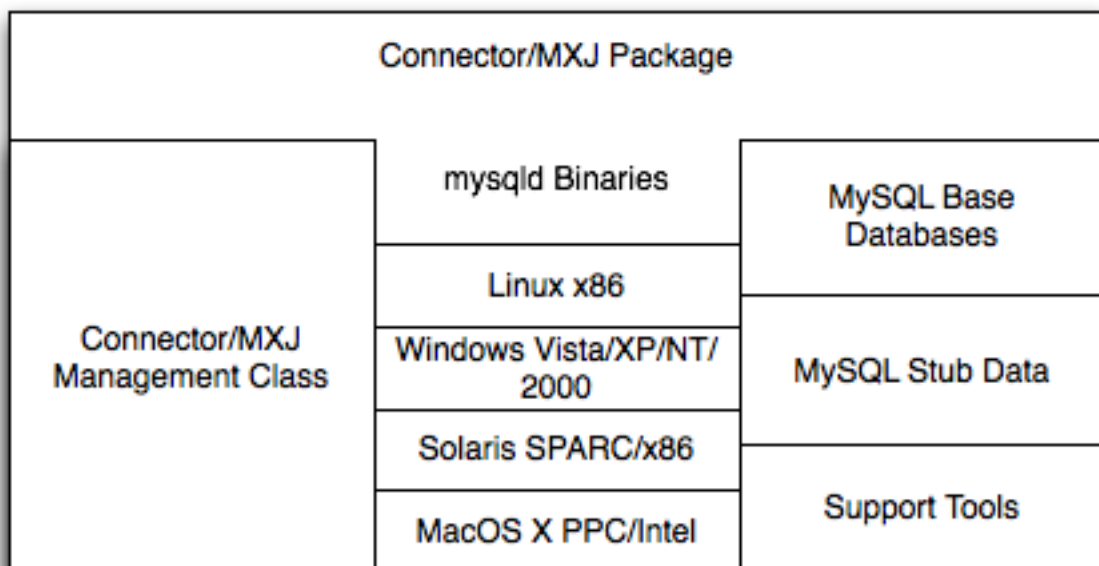

You can download sources and binaries from: <http://dev.mysql.com/downloads/connector/mxj/>

This a beta release and feedback is welcome and encouraged.

Please send questions or comments to the [MySQL and Java mailing list](#).

### 29.5.1. Connector/MXJ Overview

Connector/MXJ consists of a Java class, a copy of the `mysqld` binary for a specific list of platforms, and associated files and support utilities. The Java class controls the initialization of an instance of the embedded `mysqld` binary, and the ongoing management of the `mysqld` process. The entire sequence and management can be controlled entirely from within Java using the Connector/MXJ Java classes. You can see an overview of the contents of the Connector/MXJ package in the figure below.

It is important to note that Connector/MXJ is not an embedded version of MySQL, or a version of MySQL written as part of a Java class. Connector/MXJ works through the use of an embedded, compiled binary of `mysqld` as would normally be used when deploying a standard MySQL installation.

It is the Connector/MXJ wrapper, support classes and tools, that enable Connector/MXJ to appear as a MySQL instance.

When Connector/MXJ is initialized, the corresponding `mysqld` binary for the current platform is extracted, along with a pre-configured data directed. Both are contained within the Connector/MXJ JAR file. The `mysqld` instance is then started, with any additional options as specified during the initialization, and the MySQL database becomes accessible.

Because Connector/MXJ works in combination with Connector/J, you can access and integrate with the MySQL instance through a JDBC connection. When you have finished with the server, the instance is terminated, and, by default, any data created during the session is retained within the temporary directory created when the instance was started.

Connector/MXJ and the embedded `mysqld` instance can be deployed in a number of environments where relying on an existing database, or installing a MySQL instance would be impossible, including CD-ROM embedded database applications and temporary database requirements within a Java-based application environment.

## 29.5.2. Connector/MXJ Versions

- Connector/MXJ 5.x, currently in beta status, includes `mysqld` version 5.x and includes binaries for Linux x86, Mac OS X PPC, Windows XP/NT/2000 x86 and Solaris SPARC. Connector/MXJ 5.x requires the Connector/J 5.x package.

The exact version of `mysqld` included depends on the version of Connector/MXJ

- Connector/MXJ v5.0.3 included MySQL v5.0.22
  - Connector/MXJ v5.0.4 includes MySQL v5.0.27 (Community) or MySQL v5.0.32 (Enterprise)
  - Connector/MXJ v5.0.6 includes MySQL 5.0.37 (Community)
  - Connector/MXJ v5.0.7 includes MySQL 5.0.41 (Community) or MySQL 5.0.42 (Enterprise)
  - Connector/MXJ v5.0.8 includes MySQL 5.0.45 (Community) or MySQL 5.0.46 (Enterprise)
  - Connector/MXJ v5.0.9 includes MySQL 5.0.51a (Community) or MySQL 5.0.54 (Enterprise)
- Connector/MXJ 1.x includes `mysqld` version 4.1.13 and includes binaries for Linux x86, Windows XP/NT/2000 x86 and Solaris SPARC. Connector/MXJ 1.x requires the Connector/J 3.x package.

A summary of the different MySQL versions supplied with each Connector/MXJ release are shown in the table.

Connector/MXJ Version	MySQL Version(s)
5.0.8	5.0.45 (CS), 5.0.46 (ES)
5.0.7	5.0.41 (CS), 5.0.42 (ES)
5.0.6	5.0.37 (CS), 5.0.40 (ES)
5.0.5	5.0.37 (CS), 5.0.36 (ES)
5.0.4	5.0.27 (CS), 5.0.32 (ES)
5.0.3	5.0.22
5.0.2	5.0.19

This guide provides information on the Connector/MXJ 5.x release. For information on using the older releases, please see the documentation included with the appropriate distribution.

## 29.5.3. Connector/MXJ Installation

Connector/MXJ does not have a installation application or process, but there are some steps you can follow to make the installation and deployment of Connector/MXJ easier.

Before you start, there are some baseline requirements for

- Java Runtime Environment (v1.4.0 or newer) if you are only going to deploy the package.
- Java Development Kit (v1.4.0 or newer) if you want to build Connector/MXJ from source.
- Connector/J 5.0 or newer.

Depending on your target installation/deployment environment you may also require:

- JBoss - 4.0rc1 or newer
- Apache Tomcat - 5.0 or newer
- Sun's JMX reference implementation version 1.2.1 (from <http://java.sun.com/products/JavaManagement/>)

### 29.5.3.1. Supported Platforms

Connector/MXJ is compatible with any platform supporting Java and MySQL. By default, Connector/MXJ incorporates the `mysqld` binary for a select number of platforms which differs by version. The following platforms have been tested and working as deployment platforms. Support for all the platforms listed below is not included by default.

- Linux (i386)
- FreeBSD (i386)
- Windows NT (x86), Windows 2000 (x86), Windows XP (x86), Windows Vista (x86)
- Solaris 8, SPARC 32-bit (compatible with Solaris 8, Solaris 9 and Solaris 10 on SPARC 32-bit and 64-bit platforms)
- Mac OS X (PowerPC and Intel)

The Connector/MXJ 5.0.8 release includes `mysqld` binaries for the following platforms by as standard:

- Linux (i386)
- Windows (x86), compatible with Windows NT, Windows 2000, Windows XP, Windows Vista
- Solaris 8, SPARC 32-bit (compatible with Solaris 8, Solaris 9 and Solaris 10 on SPARC 32-bit and 64-bit platforms)
- Mac OS X (PowerPC and Intel)

For more information on packaging your own Connector/MXJ with the platforms you require, see [Section 29.5.6.1, "Creating your own Connector/MXJ Package"](#)

### 29.5.3.2. Connector/MXJ Base Installation

Because there is no formal installation process, the method, installation directory, and access methods you use for Connector/MXJ are entirely up to your individual requirements.

To perform a basic installation, choose a target directory for the files included in the Connector/MXJ package. On Unix/Linux systems you may opt to use a directory such as `/usr/local/connector-mxj`; On Windows, you may want to install the files in the base directory, `C:\Connector-MXJ`, or within the `Program Files` directory.

To install the files, for a Connector/MXJ 5.0.4 installation:

1. Download the Connector/MXJ package, either in Tar/Gzip format (ideal for Unix/Linux systems) or Zip format (Windows).
2. Extract the files from the package. This will create a directory `mysql-connector-mxj-gpl-[ver]`. Copy and optionally rename this directory to your desired location.
3. For best results, you should update your global `CLASSPATH` variable with the location of the required `jar` files.

Within Unix/Linux you can do this globally by editing the global shell profile, or on a user by user basis by editing their individual shell profile.

On Windows 2000, Windows NT and Windows XP, you can edit the global `CLASSPATH` by editing the `Environment Variables` configured through the `System` control panel.

For Connector/MXJ 5.0.6 and later you need the following JAR files in your `CLASSPATH`:

1. `mysql-connector-mxj-gpl-[ver].jar` — contains the main Connector/MXJ classes.
2. `mysql-connector-mxj-gpl-[ver]-db-files.jar` — contains the embedded `mysqld` and database files.
3. `aspectjrt.jar` — the AspectJ runtime library, located in `lib/aspectjrt.jar` in the Connector/MXJ package.
4. `mysql-connector-java-[ver]-bin.jar` — Connector/J, see [Section 29.4, “MySQL Connector/J”](#).

For Connector/MXJ 5.0.4 and later you need the following JAR files in your `CLASSPATH`:

1. `connector-mxj.jar` — contains the main Connector/MXJ classes.
2. `connector-mxj-db-files.jar` — contains the embedded `mysqld` and database files.
3. `aspectjrt.jar` — the AspectJ runtime library, located in `lib/aspectjrt.jar` in the Connector/MXJ package.
4. `mysql-connector-mxj-gpl-[ver].jar` — Connector/J, see [Section 29.4, “MySQL Connector/J”](#).

For Connector/MXJ 5.0.3 and earlier, you need the following JAR files:

1. `connector-mxj.jar`
2. `aspectjrt.jar` — the AspectJ runtime library, located in `lib/aspectjrt.jar` in the Connector/MXJ package.
3. `mysql-connector-mxj-gpl-[ver].jar` — Connector/J, see [Section 29.4, “MySQL Connector/J”](#).

### 29.5.3.3. Connector/MXJ Quick Start Guide

Once you have extracted the Connector/MXJ and Connector/J components you can run one of the sample applications that initiates a MySQL instance. You can test the installation by running the `ConnectorMXJUrlTestExample`:

```
$ java ConnectorMXJUrlTestExample
jdbc:mysql:mxj://localhost:3336/our_test_app?server.basedir>
 =/var/tmp/test-mxj&createDatabaseIfNotExist=true&server.initialize-user=true
[/var/tmp/test-mxj/bin/mysqld][--no-defaults][--port=3336][--socket=mysql.sock]>
 [--basedir=/var/tmp/test-mxj][--datadir=/var/tmp/test-mxj/data]>
 [--pid-file=/var/tmp/test-mxj/data/MysqldResource.pid]
[MysqldResource] launching mysqld (driver_launched_mysqld_1)
InnoDB: The first specified data file ./ibdata1 did not exist:
InnoDB: a new database to be created!
080220 9:40:20 InnoDB: Setting file ./ibdata1 size to 10 MB
InnoDB: Database physically writes the file full: wait...
080220 9:40:20 InnoDB: Log file ./ib_logfile0 did not exist: new to be created
InnoDB: Setting log file ./ib_logfile0 size to 5 MB
InnoDB: Database physically writes the file full: wait...
080220 9:40:20 InnoDB: Log file ./ib_logfile1 did not exist: new to be created
InnoDB: Setting log file ./ib_logfile1 size to 5 MB

SELECT VERSION()

5.0.51a

[MysqldResource] stopping mysqld (process: 2238)
080220 9:40:27 [Note] /var/tmp/test-mxj/bin/mysqld: Normal shutdown

080220 9:40:27 InnoDB: Starting shutdown...
080220 9:40:29 InnoDB: Shutdown completed; log sequence number 0 43655
080220 9:40:29 [Note] /var/tmp/test-mxj/bin/mysqld: Shutdown complete

[MysqldResource] shutdown complete
```

The above output shows an instance of MySQL starting, the necessary files being created (log files, InnoDB data files) and the MySQL database entering the running state. The instance is then shutdown by Connector/MXJ before the example terminates.

### 29.5.3.4. Deploying Connector/MXJ using Driver Launch

Connector/MXJ and Connector/J work together to enable you to launch an instance of the `mysqld` server through the use of a keyword in the JDBC connection string. Deploying Connector/MXJ within a Java application can be automated through this method, making the deployment of Connector/MXJ a simple process:

1. Download and unzip Connector/MXJ, add `mysql-connector-mxj-gpl-[ver].jar` to the `CLASSPATH`.  
If you are using Connector/MXJ v5.0.4 or later you will also need to add the `mysql-connector-mxj-gpl-[ver]-db-files.jar` file to your `CLASSPATH`.
2. To the JDBC connection string, embed the `mxj` keyword, for example: `jdbc:mysql:mxj://localhost:PORT/DB-NAME`.

For more details, see [Section 29.5.4, “Connector/MXJ Configuration”](#).

### 29.5.3.5. Deploying Connector/MXJ within JBoss

For deployment within a JBoss environment, you must configure the JBoss environment to use the Connector/MXJ component within the JDBC parameters:

1. Download Connector/MXJ and copy the `mysql-connector-mxj-gpl-[ver].jar` file to the `$JBOSS_HOME/server/default/lib` directory.  
If you are using Connector/MXJ v5.0.4 or later you will also need to copy the `mysql-connector-mxj-gpl-[ver]-db-files.jar` file to `$JBOSS_HOME/server/default/lib`.
2. Download Connector/J and copy the `mysql-connector-java-5.1.5-bin.jar` file to the `$JBOSS_HOME/server/default/lib` directory.
3. Create an MBean service xml file in the `$JBOSS_HOME/server/default/deploy` directory with any attributes set, for instance the `datadir` and `autostart`.
4. Set the JDBC parameters of your web application to use:

```
String driver = "com.mysql.jdbc.Driver";
String url = "jdbc:mysql:///test?propertiesTransform="+
 "com.mysql.management.jmx.ConnectorMXJPropertiesTransform";
String user = "root";
String password = "";
Class.forName(driver);
Connection conn = DriverManager.getConnection(url, user, password);
```

You may wish to create a separate users and database table spaces for each application, rather than using "root and test".

We highly suggest having a routine backup procedure for backing up the database files in the `datadir`.

### 29.5.3.6. Verifying Installation using JUnit

The best way to ensure that your platform is supported is to run the JUnit tests. These will test the Connector/MXJ classes and the associated components.

#### 29.5.3.6.1. JUnit Test Requirements

The first thing to do is make sure that the components will work on the platform. The `MysqldResource` class is really a wrapper for a native version of MySQL, so not all platforms are supported. At the time of this writing, Linux on the i386 architecture has been tested and seems to work quite well, as does OS X v10.3. There has been limited testing on Windows and Solaris.

Requirements:

1. JDK-1.4 or newer (or the JRE if you aren't going to be compiling the source or JSPs).
2. MySQL Connector/J version 5.0 or newer (from <http://dev.mysql.com/downloads/connector/j/>) installed and available via your `CLASSPATH`.
3. The `javax.management` classes for JMX version 1.2.1, these are present in the following application servers:
  - JBoss - 4.0rc1 or newer.

- Apache Tomcat - 5.0 or newer.
  - Sun's JMX reference implementation version 1.2.1 (from <http://java.sun.com/products/JavaManagement/>).
4. JUnit 3.8.1 (from <http://www.junit.org/>).

If building from source, All of the requirements from above, plus:

1. Ant version 1.5 or newer (download from <http://ant.apache.org/>).

### 29.5.3.6.2. Running the JUnit Tests

1. The tests attempt to launch MySQL on the port 3336. If you have a MySQL running, it may conflict, but this isn't very likely because the default port for MySQL is 3306. However, You may set the "c-mxj\_test\_port" Java property to a port of your choosing. Alternatively, you may wish to start by shutting down any instances of MySQL you have running on the target machine.

The tests suppress output to the console by default. For verbose output, you may set the "c-mxj\_test\_silent" Java property to "false".

2. To run the JUnit test suite, the \$CLASSPATH must include the following:

- JUnit
- JMX
- Connector/J
- MySQL Connector/MXJ

3. If `connector-mxj.jar` is not present in your download, unzip MySQL Connector/MXJ source archive.

```
cd mysqljmx
ant dist
```

Then add `$TEMP/cmxj/stage/connector-mxj/connector-mxj.jar` to the CLASSPATH.

4. if you have `junit`, execute the unit tests. From the command line, type:

```
java com.mysql.management.AllTestsSuite
```

The output should look something like this:

```
.....
.....
.....
Time: 259.438
OK (101 tests)
```

Note that the tests are a bit slow near the end, so please be patient.

## 29.5.4. Connector/MXJ Configuration

### 29.5.4.1. Running as part of the JDBC Driver

A feature of the MySQL Connector/J JDBC driver is the ability to specify a connection to an embedded Connector/MXJ instance through the use of the `mxj` keyword in the JDBC connection string.

In the following example, we have a program which creates a connection, executes a query, and prints the result to the System.out. The MySQL database will be deployed and started as part of the connection process, and shutdown as part of the finally block.

You can find this file in the Connector/MXJ package as `src/ConnectorMXJUrlTestExample.java`.

```

import java.io.File;
import java.sql.Connection;
import java.sql.DriverManager;

import com.mysql.management.driverlaunched.ServerLauncherSocketFactory;
import com.mysql.management.util.QueryUtil;

public class ConnectorMXJUrlTestExample {
 public static String DRIVER = "com.mysql.jdbc.Driver";

 public static String JAVA_IO_TMPDIR = "java.io.tmpdir";

 public static void main(String[] args) throws Exception {
 File ourAppDir = new File(System.getProperty(JAVA_IO_TMPDIR));
 File databaseDir = new File(ourAppDir, "test-mxj");
 int port = Integer.parseInt(System.getProperty("c-mxj_test_port", "3336"));
 String dbName = "our_test_app";

 String url = "jdbc:mysql:mxj://localhost:" + port + "/" + dbName //
 + "?" + "server.baseDir=" + databaseDir //
 + "&" + "createDatabaseIfNotExist=true" //
 + "&" + "server.initialize-user=true" //
 ;

 System.out.println(url);

 String userName = "alice";
 String password = "q93uti0opwhkd";

 Class.forName(DRIVER);
 Connection conn = null;
 try {
 conn = DriverManager.getConnection(url, userName, password);
 String sql = "SELECT VERSION()";
 String queryForString = new QueryUtil(conn).queryForString(sql);

 System.out.println("-----");
 System.out.println(sql);
 System.out.println("-----");
 System.out.println(queryForString);
 System.out.println("-----");
 System.out.flush();
 Thread.sleep(100); // wait for System.out to finish flush
 } finally {
 try {
 if (conn != null)
 conn.close();
 } catch (Exception e) {
 e.printStackTrace();
 }

 ServerLauncherSocketFactory.shutdown(databaseDir, null);
 }
 }
}

```

To run the above program, be sure to have connector-mxj.jar and Connector/J in the CLASSPATH. Then type:

```
java ConnectorMXJTestExample
```

### 29.5.4.2. Running within a Java Object

If you have a java application and wish to “embed” a MySQL database, make use of the [com.mysql.management.MysqldResource](#) class directly. This class may be instantiated with the default (no argument) constructor, or by passing in a [java.io.File](#) object representing the directory you wish the server to be “unzipped” into. It may also be instantiated with printstreams for “stdout” and “stderr” for logging.

Once instantiated, a [java.util.Map](#), the object will be able to provide a [java.util.Map](#) of server options appropriate for the platform and version of MySQL which you will be using.

The [MysqldResource](#) enables you to “start” MySQL with a [java.util.Map](#) of server options which you provide, as well as “shutdown” the database. The following example shows a simplistic way to embed MySQL in an application using plain java objects.

You can find this file in the Connector/MXJ package as [src/ConnectorMXJObjectTestExample.java](#).

```

import java.io.File;
import java.sql.Connection;
import java.sql.DriverManager;
import java.util.HashMap;
import java.util.Map;

import com.mysql.management.MysqldResource;
import com.mysql.management.MysqldResourceI;
import com.mysql.management.util.QueryUtil;

```

```

public class ConnectorMXJObjectTestExample {
 public static final String DRIVER = "com.mysql.jdbc.Driver";

 public static final String JAVA_IO_TMPDIR = "java.io.tmpdir";

 public static void main(String[] args) throws Exception {
 File ourAppDir = new File(System.getProperty(JAVA_IO_TMPDIR));
 File databaseDir = new File(ourAppDir, "mysql-mxj");
 int port = Integer.parseInt(System.getProperty("c-mxj_test_port",
 "3336"));
 String userName = "alice";
 String password = "q93uti0opwhkd";

 MysqlResource mysqlResource = startDatabase(databaseDir, port,
 userName, password);

 Class.forName(DRIVER);
 Connection conn = null;
 try {
 String dbName = "our_test_app";
 String url = "jdbc:mysql://localhost:" + port + "/" + dbName //
 + "?" + "createDatabaseIfNotExist=true" //
 ;
 conn = DriverManager.getConnection(url, userName, password);
 String sql = "SELECT VERSION()";
 String queryForString = new QueryUtil(conn).queryForString(sql);

 System.out.println("-----");
 System.out.println(sql);
 System.out.println("-----");
 System.out.println(queryForString);
 System.out.println("-----");
 System.out.flush();
 Thread.sleep(100); // wait for System.out to finish flush
 } finally {
 try {
 if (conn != null) {
 conn.close();
 }
 } catch (Exception e) {
 e.printStackTrace();
 }
 try {
 mysqlResource.shutdown();
 } catch (Exception e) {
 e.printStackTrace();
 }
 }
 }

 public static MysqlResource startDatabase(File databaseDir, int port,
 String userName, String password) {
 MysqlResource mysqlResource = new MysqlResource(databaseDir);

 Map database_options = new HashMap();
 database_options.put(MysqlResourceI.PORT, Integer.toString(port));
 database_options.put(MysqlResourceI.INITIALIZE_USER, "true");
 database_options.put(MysqlResourceI.INITIALIZE_USER_NAME, userName);
 database_options.put(MysqlResourceI.INITIALIZE_PASSWORD, password);

 mysqlResource.start("test-mysql-thread", database_options);

 if (!mysqlResource.isRunning()) {
 throw new RuntimeException("MySQL did not start.");
 }

 System.out.println("MySQL is running.");

 return mysqlResource;
 }
}

```

### 29.5.4.3. Setting server options

Of course there are many options we may wish to set for a MySQL database. These options may be specified as part of the JDBC connection string simply by prefixing each server option with `server..` In the following example we set two driver parameters and two server parameters:

```

String url = "jdbc:mysql://" + hostColonPort + "/"
 + "?"
 + "cacheServerConfiguration=true"
 + "&"
 + "useLocalSessionState=true"
 + "&"
 + "serverbasedir=/opt/myapp/db"
 + "&"
 + "server.datadir=/mnt/bigdisk/myapp/data";

```

Starting with Connector/MXJ 5.0.6 you can use the `initializer-user` property to a connection string. If set to true, the de-

fault anonymous and root users will be removed and the user/password combination from the connection URL will be used to create a new user. For example:

```
String url = "jdbc:mysql:mxj://localhost:" + port
+ "/alice_db"
+ "?server.dataDir=" + dataDir.getPath()
+ "&server.initialize-user=true"
+ "&createDatabaseIfNotExist=true"
;
```

## 29.5.5. Connector/MXJ Reference

The following sections include detailed information on the different API interfaces to Connector/MXJ.

### 29.5.5.1. MysqlResource Constructors

The `MysqlResource` class supports three different constructor forms:

- ```
public MysqlResource(File baseDir, File dataDir, String mysqlVersionString, PrintStream out, PrintStream err)
```

Enables you to set the base directory, data directory, select a server by its version string, standard out and standard error.
- ```
public MysqlResource(File baseDir, File dataDir, String mysqlVersionString)
```

Enables you to set the base directory, data directory and select a server by its version string. Output for standard out and standard err are directed to `System.out` and `System.err`.
- ```
public MysqlResource(File baseDir, File dataDir)
```

Enables you to set the base directory and data directory. The default MySQL version is selected, and output for standard out and standard err are directed to `System.out` and `System.err`.
- ```
public MysqlResource(File baseDir);
```

Allows the setting of the "basedir" to deploy the MySQL files to. Output for standard out and standard err are directed to `System.out` and `System.err`.
- ```
public MysqlResource();
```

The basedir is defaulted to a subdirectory of the `java.io.tmpdir`. Output for standard out and standard err are directed to `System.out` and `System.err`;

29.5.5.2. MysqlResource Methods

`MysqlResource` API includes the following methods:

- ```
void start(String threadName, Map mysqlArgs);
```

Deploys and starts MySQL. The "threadName" string is used to name the thread which actually performs the execution of the MySQL command line. The map is the set of arguments and their values to be passed to the command line.
- ```
void shutdown();
```

Shuts down the MySQL instance managed by the `MysqlResource` object.
- ```
Map getServerOptions();
```

Returns a map of all the options and their current (or default, if not running) options available for the MySQL database.
- ```
boolean isRunning();
```

Returns true if the MySQL database is running.
- ```
boolean isReadyForConnections();
```

Returns true once the database reports that is ready for connections.

- `void setKillDelay(int millis);`

The default “Kill Delay” is 30 seconds. This represents the amount of time to wait between the initial request to shutdown and issuing a “force kill” if the database has not shutdown by itself.

- `void addCompletionListener(Runnable listener);`

Allows for applications to be notified when the server process completes. Each "listener" will be fired off in its own thread.

- `String getVersion();`

Returns the version of MySQL.

- `void setVersion(int MajorVersion, int minorVersion, int patchLevel);`

The standard distribution comes with only one version of MySQL packaged. However, it is possible to package multiple versions, and specify which version to use.

## 29.5.6. Connector/MXJ Notes and Tips

This section contains notes and tips on using the Connector/MXJ component within your applications.

### 29.5.6.1. Creating your own Connector/MXJ Package

If you want to create a custom Connector/MXJ package that includes a specific `mysqld` version or platform then you must extract and rebuild the `mysql-connector-mxj.jar` (Connector/MXJ v5.0.3 or earlier) or `mysql-connector-mxj-gpl-[ver]-db-files.jar` (Connector/MXJ v5.0.4 or later) file.

First, you should create a new directory into which you can extract the current `connector-mxj.jar`:

```
shell> mkdir custom-mxj
shell> cd custom-mxj
shell> jar -xf connector-mxj.jar
shell> ls
5-0-22/
ConnectorMXJObjectTestExample.class
ConnectorMXJUrlTestExample.class
META-INF/
TestDb.class
com/
kill.exe
```

If you are using Connector/MXJ v5.0.4 or later, you should unpack the `connector-mxj-db-files.jar`:

```
shell> mkdir custom-mxj
shell> cd custom-mxj
shell> jar -xf connector-mxj-db-files.jar
shell> ls
5-0-51a/
META-INF/
connector-mxj.properties
```

The MySQL version directory, `5-0-22` or `5-0-51a` in the preceding examples, contains all of the files used to create an instance of MySQL when Connector/MXJ is executed. All of the files in this directory are required for each version of MySQL that you want to embed. Note as well the format of the version number, which uses hyphens instead of periods to separate the version number components.

Within the version specific directory are the platform specific directories, and archives of the `data` and `share` directory required by MySQL for the various platforms. For example, here is the listing for the default Connector/MXJ package:

```
shell>> ls
Linux-i386/
META-INF/
Mac_OS_X-ppc/
SunOS-sparc/
Win-x86/
com/
data_dir.jar
share_dir.jar
win_share_dir.jar
```

Platform specific directories are listed by their OS and platform - for example the `mysqld` for Mac OS X PowerPC is located within the `Mac_OS_X-ppc` directory. You can delete directories from this location that you do not require, and add new directories for additional platforms that you want to support.

To add a platform specific `mysqld`, create a new directory with the corresponding name for your operating system/platform. For example, you could add a directory for Mac OS X/Intel using the directory `Mac_OS_X-i386`.

On Unix systems, you can determine the platform using `uname`:

```
shell> uname -p
i386
```

In Connector/MXJ v5.0.9 and later, an additional `platform-map.properties` file is used to associate a specific platform and operating system combination with the directory in which the `mysqld` for that combination is located. The determined operating system and platform are on the left, and the directory name where the appropriate `mysqld` is located is on the right. You can see a sample of the file below:

```
Linux-i386=Linux-i386
Linux-x86=Linux-i386
Linux-i686=Linux-i386
Linux-x86_64=Linux-i386
Linux-ia64=Linux-i386

#Linux-ppc=Linux-ppc
#Linux-ppc64=Linux-ppc

Mac_OS_X-i386=Mac_OS_X-i386
Mac_OS_X-ppc=Mac_OS_X-ppc
Rhapsody-PowerPC=Mac_OS_X-ppc
#Mac_OS-PowerPC=
#macos-PowerPC=
#MacOS-PowerPC=

SunOS-sparc=SunOS-sparc
Solaris-sparc=SunOS-sparc
SunOS-x86=SunOS-x86
Solaris-x86=SunOS-x86

FreeBSD-x86=FreeBSD-x86

Windows_Vista-x86=Win-x86
Windows_2003-x86=Win-x86
Windows_XP-x86=Win-x86
Windows_2000-x86=Win-x86
Windows_NT-x86=Win-x86
Windows_NT_(unknown)-x86=Win-x86
```

Now you need to download or compile `mysqld` for the MySQL version and platform you want to include in your custom `connector-mxj.jar` package into the new directory.

Create a file called `version.txt` in the OS/platform directory you have just created that contains the version string/path of the `mysqld` binary. For example:

```
mysql-5.0.22-osx10.3-i386/bin/mysqld
```

You can now recreate the `connector-mxj.jar` file with the added `mysqld`:

```
shell> cd custom-mxj
shell> jar -cf ../connector-mxj.jar *
```

For Connector/MXJ v5.0.4 and later, you should repackage to the `connector-mxj-db-files.jar`:

```
shell> cd custom-mxj
shell> jar -cf ../mysql-connector-mxj-gpl-[ver]-db-files.jar *
```

You should test this package using the steps outlined in [Section 29.5.3.3, “Connector/MXJ Quick Start Guide”](#).

### Note

Because the `mysql-connector-mxj-gpl-[ver]-db-files.jar` file is separate from the main Connector/MXJ classes you can distribute different `mysql-connector-mxj-gpl-[ver]-db-files.jar` files to different hosts or for different projects without having to create a completely new main `mysql-connector-mxj-gpl-[ver].jar` file for each one.

## 29.5.6.2. Deploying Connector/MXJ with a pre-configured database

To include a pre-configured/populated database within your Connector/MXJ JAR file you must create a custom `data_dir.jar` file, as included within the main `connector-mxj.jar` (Connector/MXJ 5.0.3 or earlier) or `mysql-connector-mxj-gpl-[ver]-db-files.jar` (Connector/MXJ 5.0.4 or later) file:

1. First extract the `connector-mxj.jar` or `mysql-connector-gpl-[ver]-db-files.jar` file, as outlined in the previous section (see [Section 29.5.6.1](#), “Creating your own Connector/MXJ Package”).
2. First, create your database and populate the database with the information you require in an existing instance of MySQL - including Connector/MXJ instances. Data file formats are compatible across platforms.
3. Shutdown the instance of MySQL.
4. Create a JAR file of the data directory and databases that you want to include your Connector/MXJ package. You should include the `mysql` database, which includes user authentication information, in addition to the specific databases you want to include. For example, to create a JAR of the `mysql` and `mxjtest` databases:

```
shell> jar -cf ../data_dir.jar mysql mxjtest
```

5. For Connector/MXJ 5.0.3 or earlier, copy the `data_dir.jar` file into the extracted `connector-mxj.jar` directory, and then create an archive for `connector-mxj.jar`.

For Connector/MXJ 5.0.4 or later, copy the `data_dir.jar` file into the extracted `mysql-connector-mxj-gpl-[ver]-db-files.jar` directory, and then create an archive for `mysql-connector-mxj-gpl-[ver]-files.jar`.

Note that if you are create databases using the InnoDB engine, you must include the `ibdata.*` and `ib_logfile*` files within the `data_dir.jar` archive.

### 29.5.6.3. Running within a JMX Agent (custom)

As a JMX MBean, MySQL Connector/MXJ requires a JMX v1.2 compliant MBean container, such as JBoss version 4. The MBean will use the standard JMX management APIs to present (and allow the setting of) parameters which are appropriate for that platform.

If you are not using the SUN Reference implementation of the JMX libraries, you should skip this section. Or, if you are deploying to JBoss, you also may wish to skip to the next section.

We want to see the `MysqldDynamicMBean` in action inside of a JMX agent. In the `com.mysql.management.jmx.sunri` package is a custom JMX agent with two MBeans:

1. the `MysqldDynamicMBean`, and
2. a `com.sun.jdmk.comm.HtmlAdaptorServer`, which provides a web interface for manipulating the beans inside of a JMX agent.

When this very simple agent is started, it will allow a MySQL database to be started and stopped with a web browser.

1. Complete the testing of the platform as above.
  - current JDK, JUnit, Connector/J, MySQL Connector/MXJ
  - this section *requires* the SUN reference implementation of JMX
  - `PATH`, `JAVA_HOME`, `ANT_HOME`, `CLASSPATH`

2. If not building from source, skip to next step

rebuild with the "sunri.present"

```
ant -Dsunri.present=true dist
re-run tests:
java junit.textui.TestRunner com.mysql.management.AllTestsSuite
```

3. launch the test agent from the command line:

```
java com.mysql.management.jmx.sunri.MysqldTestAgentSunHtmlAdaptor &
```

4. from a browser:

```
http://localhost:9092/
```

5. under MysqlAgent,

```
select "name=mysqlid"
```

6. Observe the MBean View
7. scroll to the bottom of the screen press the STARTMYSQLD button
8. click [Back to MBean View](#)
9. scroll to the bottom of the screen press STOPMYSQLD button
10. kill the java process running the Test Agent (jmx server)

#### 29.5.6.4. Deployment in a standard JMX Agent environment (JBoss)

Once there is confidence that the MBean will function on the platform, deploying the MBean inside of a standard JMX Agent is the next step. Included are instructions for deploying to JBoss.

1. Ensure a current version of java development kit (v1.4.x), see above.
  - Ensure `JAVA_HOME` is set (JBoss requires `JAVA_HOME`)
  - Ensure `JAVA_HOME/bin` is in the `PATH` (You will NOT need to set your `CLASSPATH`, nor will you need any of the jars used in the previous tests).
2. Ensure a current version of JBoss (v4.0RC1 or better)

```
http://www.jboss.org/index.html
select "Downloads"
select "jboss-4.0.zip"
pick a mirror
unzip ~/dload/jboss-4.0.zip
create a JBOSS_HOME environment variable set to the unzipped directory
unix only:
cd $JBOSS_HOME/bin
chmod +x *.sh
```

3. Deploy (copy) the `connector-mxj.jar` to `$JBOSS_HOME/server/default/lib`.
4. Deploy (copy) `mysql-connector-java-3.1.4-beta-bin.jar` to `$JBOSS_HOME/server/default/lib`.
5. Create a `mxjtest.war` directory in `$JBOSS_HOME/server/default/deploy`.
6. Deploy (copy) `index.jsp` to `$JBOSS_HOME/server/default/deploy/mxjtest.war`.
7. Create a `mysqlid-service.xml` file in `$JBOSS_HOME/server/default/deploy`.

```
<?xml version="1.0" encoding="UTF-8"?>
<server>
 <mbean code="com.mysql.management.jmx.jboss.JBossMysqlidDynamicMBean"
 name="mysql:type=service,name=mysqlid">
 <attribute name="datadir">/tmp/xxx_data_xxx</attribute>
 <attribute name="autostart">true</attribute>
 </mbean>
</server>
```

8. Start jboss:
  - on unix: `$JBOSS_HOME/bin/run.sh`
  - on windows: `%JBOSS_HOME%\bin\run.bat`

Be ready: JBoss sends a lot of output to the screen.

9. When JBoss seems to have stopped sending output to the screen, open a web browser to: <http://localhost:8080/jmx-console>
10. Scroll down to the bottom of the page in the `mysql` section, select the bulleted `mysqlid` link.
11. Observe the JMX MBean View page. MySQL should already be running.

12. (If "autostart=true" was set, you may skip this step.) Scroll to the bottom of the screen. You may press the INVOKE button to stop (or start) MySQL observe `Operation completed successfully without a return value`. Click `Back to MBean View`
13. To confirm MySQL is running, open a web browser to `http://localhost:8080/mxjtest/` and you should see that

```
SELECT 1
```

returned with a result of

```
1
```

14. Guided by the `$JBOSS_HOME/server/default/deploy/mxjtest.war/index.jsp` you will be able to use MySQL in your Web Application. There is a `test` database and a `root` user (no password) ready to experiment with. Try creating a table, inserting some rows, and doing some selects.
15. Shut down MySQL. MySQL will be stopped automatically when JBoss is stopped, or: from the browser, scroll down to the bottom of the MBean View press the stop service INVOKE button to halt the service. Observe `Operation completed successfully without a return value`. Using `ps` or `task manager` see that MySQL is no longer running

As of 1.0.6-beta version is the ability to have the MBean start the MySQL database upon start up. Also, we've taken advantage of the JBoss life-cycle extension methods so that the database will gracefully shut down when JBoss is shutdown.

## 29.5.7. Connector/MXJ Support

There are a wide variety of options available for obtaining support for using Connector/MXJ. You should contact the Connector/MXJ community for help before reporting a potential bug or problem. See [Section 29.5.7.1, "Connector/MXJ Community Support"](#).

### 29.5.7.1. Connector/MXJ Community Support

MySQL AB provides assistance to the user community by means of a number of mailing lists and web based forums.

You can find help and support through the [MySQL and Java](#) mailing list.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.6.1, "MySQL Mailing Lists"](#).

Community support from experienced users is also available through the [MyODBC Forum](#). You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.6.2, "MySQL Community Support at the MySQL Forums"](#).

### 29.5.7.2. How to Report Connector/MXJ Problems

If you encounter difficulties or problems with Connector/MXJ, contact the Connector/MXJ community [Section 29.5.7.1, "Connector/MXJ Community Support"](#).

If reporting a problem, you should ideally include the following information with the email:

- Operating system and version
- Connector/MXJ version
- MySQL server version
- Copies of error messages or other unexpected output
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

If you believe the problem to be a bug, then you must report the bug through <http://bugs.mysql.com/>.

### 29.5.7.3. Connector/MXJ Change History

The Connector/MXJ Change History (Changelog) is located with the main Changelog for MySQL. See [Section C.6, "MySQL Con-](#)

[nector/MXJ Change History](#)".

## 29.6. Connector/PHP

The PHP distribution and documentation are available from the PHP Web site. MySQL provides the `mysql` and `mysql_i` extensions for the Windows operating system on <http://dev.mysql.com/downloads/connector/php/> for MySQL version 4.1.16 and higher, MySQL 5.0.18, and MySQL 5.1. You can find information why you should preferably use the extensions provided by MySQL on that page. For platforms other than Windows, you should use the `mysql` or `mysql_i` extensions shipped with the PHP sources. See [Section 28.3, "MySQL PHP API"](#).

---

## Chapter 30. MySQL Proxy

The MySQL Proxy is an application that communicates over the network using the MySQL Network Protocol and provides communication between one or more MySQL servers and one or more MySQL clients. In the most basic configuration, MySQL Proxy simply passes on queries from the client to the MySQL Server and returns the responses from the MySQL Server to the client.

Because MySQL Proxy uses the MySQL network protocol, any MySQL compatible client (include the command line client, any clients using the MySQL client libraries, and any connector that supports the MySQL network protocol) can connect to the proxy without modification.

In addition to the basic pass-through configuration, the MySQL Proxy is also capable of monitoring and altering the communication between the client and the server. This interception of the queries enables you to add profiling, and the interception of the exchanges is scriptable using the Lua scripting language.

By intercepting the queries from the client, the proxy can insert additional queries into the list of queries sent to the server, and remove the additional results when they are returned by the server. Using this functionality you can add informational statements to each query, for example to monitor their execution time or progress, and separately log the results, while still returning the results from the original query to the client.

The proxy allows you to perform additional monitoring, filtering or manipulation on queries without you having to make any modifications to the client and without the client even being aware that it is communicating with anything but a genuine MySQL server.

### Warning

MySQL Proxy is currently an Alpha release and should not be used within production environments.

### Important

MySQL Proxy is compatible with MySQL 5.0.x or later. Testing has not been performed with Version 4.1. Please provide feedback on your experiences via the [MySQL Proxy Forum](#).

## 30.1. MySQL Proxy Supported Platforms

MySQL Proxy is currently available as a pre-compiled binary for the following platforms:

- Linux (including RedHat, Fedora, Debian, SuSE) and derivatives.
- Mac OS X
- FreeBSD
- IBM AIX
- Sun Solaris

Other Unix/Linux platforms not listed should be compatible by using the source package and building MySQL Proxy locally.

System requirements for the MySQL Proxy application are the same as the main MySQL server. Currently MySQL Proxy is compatible only with MySQL 5.0.1 and later. MySQL Proxy is provided as a standalone, statically linked binary. You do not need to have MySQL or Lua installed.

## 30.2. Installing MySQL Proxy

You have three choices for installing MySQL Proxy:

- Pre-compiled binaries are available for a number of different platforms. See [Section 30.2.1, “Installing MySQL Proxy from a binary distribution”](#).
- You can install from the source code if you want to build on an environment not supported by the binary distributions. See [Section 30.2.2, “Installing MySQL Proxy from a source distribution”](#).
- The latest version of the MySQL proxy source code is available through a development repository is the best way to stay up to date with the latest fixes and revisions. See [Section 30.2.3, “Installing MySQL Proxy from the Subversion repository”](#).

### 30.2.1. Installing MySQL Proxy from a binary distribution

If you download the binary packages then you need only to extract the package and then copy the `mysql-proxy` file to your desired location. For example:

```
$ tar xzf mysql-proxy-0.5.0.tar.gz
$ cp ./mysql-proxy-0.5.0/sbin/mysql-proxy /usr/local/sbin
```

### 30.2.2. Installing MySQL Proxy from a source distribution

If you have downloaded the source package then you will need to compile the MySQL Proxy before using it. To build you will need to have the following installed:

- libevent 1.x or higher (1.3b or later is preferred)
- lua 5.1.x or higher
- glib2 2.6.0 or higher
- pkg-config
- MySQL 5.0.x or higher developer files

#### Note

On some operating systems you may need to manually build the required components to get the latest version. If you are having trouble compiling MySQL Proxy then consider using one of the binary distributions.

Once these components are installed, you need to configure and then build:

```
$ tar xzf mysql-proxy-0.5.0.tar.gz
$ cd mysql-proxy-0.5.0
$./configure
$ make
```

If you want to test the build, then use the `check` target to `make`:

```
$ make check
```

The tests try to connect to `localhost` using the `root` user. If you need to provide a password, set the `MYSQL_PASSWORD` environment variable:

```
$ MYSQL_PASSWORD=root_pwd make check
```

You can install using the `install` target:

```
$ make install
```

By default `mysql-proxy` is installed into `/usr/local/sbin/mysql-proxy`. The Lua example scripts are copied into `/usr/local/share`.

### 30.2.3. Installing MySQL Proxy from the Subversion repository

The MySQL Proxy source is available through a public Subversion repository and is the quickest way to get hold of the latest releases and fixes.

To build from the Subversion repository, you need the following components already installed:

- Subversion 1.3.0 or higher
- `libtool` 1.5 or higher
- `autoconf` 2.56 or higher
- `automake` 1.9 or higher
- `libevent` 1.x or higher (1.3b or later is preferred)

- lua 5.1.x or higher
- glib2 2.4.0 or higher
- pkg-config
- MySQL 5.0.x or higher developer files

To checkout a local copy of the Subversion repository, use `svn`:

```
$ svn co http://svn.MySQL.com/svnpublic/mysql-proxy/ mysql-proxy
```

The above command will download a complete version of the Subversion repository for `mysql-proxy`. The main source files are located within the `trunk` subdirectory. The configuration scripts need to be generated before you can configure and build `mysql-proxy`. The `autogen.sh` script will generate the configuration scripts for you:

```
$ sh ./autogen.sh
```

The script creates the standard `configure` script, which you can then use to configure and build with `make`:

```
$./configure
$ make
$ make install
```

If you want to create a standalone source distribution, identical to the source distribution available for download:

```
$ make distcheck
```

The above will create the file `mysql-proxy-0.5.0.tar.gz` within the current directory.

## 30.3. MySQL Proxy Command-Line Options

To start `mysql-proxy` you can just run the command directly. However, for most situations you will want to specify at the very least the address/hostname and port number of the backend MySQL server to which the MySQL Proxy should pass on queries.

You can get a list of the supported command-line options using the `--help-all` command-line option. The majority of these options set up the environment, either in terms of the address/port number that `mysql-proxy` should listen on for connections, or the onward connection to a MySQL server. A full description of the options is shown below:

- `--help-all` — show all help options.
- `--help-admin` — show options for the admin-module.
- `--help-proxy` — Show options for the proxy-module.
- `--admin-address=host:port` — specify the hostname (or IP address) and port for the administration port. The default is `localhost:4041`.
- `--proxy-address=host:port` — the listening hostname (or IP address) and port of the proxy server. The default is `localhost:4040`.
- `--proxy-read-only-address=host:port` — the listening hostname (or IP address) and port of the proxy server for read-only connections. The default is `localhost:4042`.
- `--proxy-backend-addresses=host:port` — the hostname (or IP address) and port of the MySQL server to connect to. You can specify multiple backend servers by supplying multiple options. Clients are connected to each backend server in round-robin fashion. For example, if you specify two servers A and B, the first client connection will go to server A; the second client connection to server B and the third client connection to server A.
- `--proxy-skip-profiling` — disables profiling of queries (tracking time statistics). The default is for tracking to be enabled.
- `--proxy-fix-bug-25371` — gets round an issue when connecting to a MySQL server later than 5.1.12 when using a MySQL client library of any earlier version.
- `--proxy-lua-script=file` — specify the Lua script file to be loaded. Note that the script file is not physically loaded and parsed until a connection is made. Also note that the specified Lua script is reloaded for each connection; if the content of

the Lua script changes while `mysql-proxy` is running then the updated content will automatically be used when a new connection is made.

- `--daemon` — starts the proxy in daemon mode.
- `--pid-file=file` — sets the name of the file to be used to store the process ID.
- `--version` — show the version number.

The most common usage is as a simple proxy service (i.e. without addition scripting). For basic proxy operation you must specify at least one `proxy-backend-addresses` option to specify the MySQL server to connect to by default:

```
$ mysql-proxy
--proxy-backend-addresses=MySQL.example.com:3306
```

The default proxy port is `4040`, so you can connect to your MySQL server through the proxy by specifying the hostname and port details:

```
$ mysql --host=localhost --port=4040
```

If your server requires authentication information then this will be passed through natively without alteration by `mysql-proxy`, so you must also specify the authentication information if required:

```
$ mysql --host=localhost --port=4040 \
--user=username --password=password
```

You can also connect to a read-only port (which filters out `UPDATE` and `INSERT` queries) by connecting to the read-only port. By default the hostname is the default, and the port is `4042`, but you can alter the host/port information by using the `-proxy-read-only-address` command-line option.

For more detailed information on how to use these command line options, and `mysql-proxy` in general in combination with Lua scripts, see [Section 30.5, “Using MySQL Proxy”](#).

## 30.4. MySQL Proxy Scripting

You can control how MySQL Proxy manipulates and works with the queries and results that are passed on to the MySQL server through the use of the embedded Lua scripting language. You can find out more about the Lua programming language from the [Lua Website](#).

The primary interaction between MySQL Proxy and the server is provided by defining one or more functions through an Lua script. A number of functions are supported, according to different events and operations in the communication sequence between a client and one or more backend MySQL servers:

- `connect_server()` — this function is called each time a connection is made to MySQL Proxy from a client. You can use this function during load-balancing to intercept the original connection and decide which server the client should ultimately be attached to. If you don't define a special solution, then a simple round-robin style distribution is used by default.
- `read_handshake()` — this function is called when the initial handshake information is returned by the server. You can capture the handshake information returned and provide additional checks before the authorization exchange takes place.
- `read_auth()` — this function is called when the authorization packet (username, password, default database) are submitted by the client to the server for authentication.
- `read_auth_result()` — this function is called when the server returns an authorization packet to the client indicating whether the authorization succeeded.
- `read_query()` — this function is called each time a query is sent by the client to the server. You can use this to edit and manipulate the original query, including adding new queries before and after the original statement. You can also use this function to return information directly to the client, bypassing the server, which can be useful to filter unwanted queries or queries that exceed known limits.
- `read_query_result()` — this function is called each time a result is returned from the server, providing you have manually injected queries into the query queue. If you have not explicitly inject queries within the `read_query()` function then this function is not triggered. You can use this to edit the result set, or to remove or filter the result sets generated from additional queries you injected into the queue when using `read_query()`.

The table below describes the direction of flow of information at the point when the function is triggered.

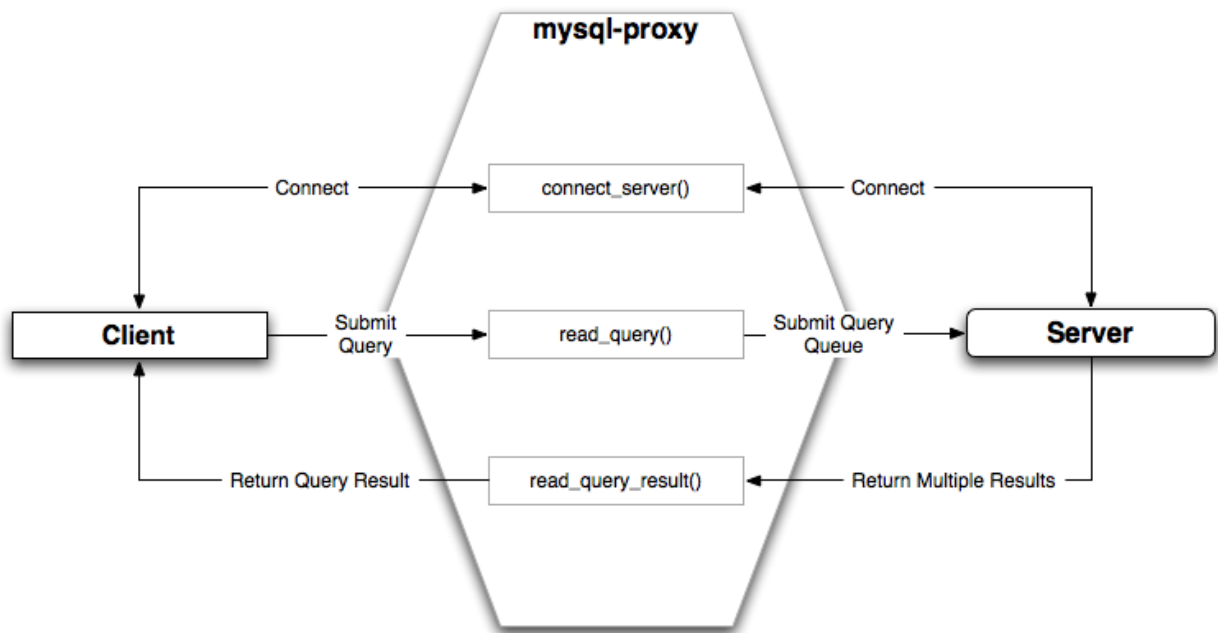

Function	Supplied Information	Direction
<code>connect_server()</code>	None	Client to Server
<code>read_handshake()</code>	Handshake packet	Server to Client
<code>read_auth()</code>	Authorization packet	Client to Server
<code>read_auth_result()</code>	Authorization response	Server to Client
<code>read_query()</code>	Query	Client to Server
<code>read_query_result()</code>	Query result	Server to Client

By default, all functions return a result that indicates that the data should be passed on to the client or server (depending on the direction of the information being transferred). This return value can be overridden by explicitly returning a constant indicating that a particular response should be sent. For example, it is possible to construct result set information by hand within `read_query()` and to return the resultset directly to the client without ever sending the original query to the server.

In addition to these functions, a number of built-in structures provide control over how MySQL Proxy forwards on queries and returns the results by providing a simplified interface to elements such as the list of queries and the groups of result sets that are returned.

### 30.4.1. Proxy Scripting Sequence During Query Injection

The figure below gives an example of how the proxy might be used when injecting queries into the query queue. Because the proxy sits between the client and MySQL server, what the proxy sends to the server, and the information that the proxy ultimately returns to the client do not have to match or correlate. Once the client has connected to the proxy, the following sequence occurs for each individual query sent by the client.

1. The client submits one query to the proxy, the `read_query()` function within the proxy is triggered. The function adds the query to the query queue.
2. Once manipulation by `read_query()` has completed, the queries are submitted, sequentially, to the MySQL server.
3. The MySQL server returns the results from each query, one result set for each query submitted. The `read_query_result()` function is triggered for each result set, and each invocation can decide which result set to return to the client

For example, you can queue additional queries into the global query queue to be processed by the server. This can be used to add statistical information by adding queries before and after the original query, changing the original query:

```
SELECT * FROM City;
```

Into a sequence of queries:

```
SELECT NOW();
SELECT * FROM City;
SELECT NOW();
```

You can also modify the original statement, for example to add `EXPLAIN` to each statement executed to get information on how the statement was processed, again altering our original SQL statement into a number of statements:

```
SELECT * FROM City;
EXPLAIN SELECT * FROM City;
```

In both of these examples, the client would have received more result sets than expected. Regardless of how you manipulate the incoming query and the returned result, the number of queries returned by the proxy must match the number of original queries sent by the client.

You could adjust the client to handle the multiple result sets sent by the proxy, but in most cases you will want the existence of the proxy to remain transparent. To ensure that the number of queries and result sets match, you can use the MySQL Proxy `read_query_result()` to extract the additional result set information and return only the result set the client originally requested back to the client. You can achieve this by giving each query that you add to the query queue a unique ID, and then filter out queries that do not match the original query ID when processing them with `read_query_result()`.

## 30.4.2. Internal Structures

There are a number of internal structures within the scripting element of MySQL Proxy. The primary structure is `proxy` and this provides an interface to the many common structures used throughout the script, such as connection lists and configured backend servers. Other structures, such as the incoming packet from the client and result sets are only available within the context of one of the scriptable functions.

Attribute	Description
<code>connection</code>	A structure containing the active client connections. For a list of attributes, see <code>proxy.connection</code> .
<code>servers</code>	A structure containing the list of configured backend servers. For a list of attributes, see <code>proxy.backends</code> .
<code>queries</code>	A structure containing the queue of queries that will be sent to the server during a single client query. For a list of attributes, see <code>proxy.queries</code> .
<code>PROXY_VERSION</code>	The version number of MySQL Proxy, encoded in hex. You can use this to check that the version number supports a particular option from within the Lua script. Note that the value is encoded as a hex value, so to check the version is at least 0.5.1 you compare against <code>0x00501</code> .

### `proxy.connection`

The `proxy.connection` object is read only, and provides information about the current connection.

Attribute	Description
<code>thread_id</code>	The thread ID of the connection.
<code>backend_ndx</code>	The ID of the server used for this connection. This is an ID valid against the list of configured servers available through the <code>proxy.backends</code> object.

### `proxy.backends`

The `proxy.backends` table is partially writable and contains an array of all the configured backend servers and the server metadata (IP address, status, etc.). You can determine the array index of the current connection using `proxy.connection["backend_ndx"]` which is the index into this table of the backend server being used by the active connection.

The attributes for each entry within the `proxy.backends` table are shown in this table.

Attribute	Description
<code>address</code>	The hostname/port combination used for this connection
<code>connected_clients</code>	The number of clients currently connected.
<code>state</code>	The status of the backend server. See <a href="#">Section 30.4.2, “Internal Structures” [1811]</a>

### proxy.queries

The `proxy.queries` object is a queue representing the list of queries to be sent to the server. The queue is not populated automatically, but if you do not explicitly populate the queue then queries are passed on to the backend server verbatim. Also, if you do not populate the query queue by hand, then the `read_query_result()` function is not triggered.

The following methods are supported for populating the `proxy.queries` object.

Function	Description
<code>append(id,packet)</code>	Appends a query to the end of the query queue. The <code>id</code> is an integer identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet.
<code>prepend(id,packet)</code>	Prepends a query to the query queue. The <code>id</code> is an identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet.
<code>reset()</code>	Empties the query queue.
<code>len()</code>	Returns the number of query packets in the queue.

For example, you could append a query packet to the `proxy.queries` queue by using the `append()`:

```
proxy.queries:append(1,packet)
```

### Proxy Return State Constants

The following constants are used internally by the proxy to specify the response to send to the client or server. All constants are exposed as values within the main `proxy` table.

Constant	Description
<code>PROXY_SEND_QUERY</code>	Causes the proxy to send the current contents of the queries queue to the server.
<code>PROXY_SEND_RESULT</code>	Causes the proxy to send a result set back to the client.
<code>PROXY_IGNORE_RESULT</code>	Causes the proxy to drop the result set (nothing is returned to the client).

As constants, these entities are available without qualification in the Lua scripts. For example, at the end of the `read_query_result()` you might return `PROXY_IGNORE_RESULT`:

```
return proxy.PROXY_IGNORE_RESULT
```

### Packet State Constants

The following states describe the status of a network packet. These items are entries within the main `proxy` table.

Constant	Description
<code>MYSQLD_PACKET_OK</code>	The packet is OK.
<code>MYSQLD_PACKET_ERR</code>	The packet contains error information.
<code>MYSQLD_PACKET_RAW</code>	The packet contains raw data.

### Backend State/Type Constants

The following constants are used either to define the status of the backend server (the MySQL server to which the proxy is connected) or the type of backend server. These items are entries within the main `proxy` table.

Constant	Description
<code>BACKEND_STATE_UNKNOWN</code>	The current status is unknown.
<code>BACKEND_STATE_UP</code>	The backend is known to be up (available).
<code>BACKEND_STATE_DOWN</code>	The backend is known to be down (unavailable).
<code>BACKEND_TYPE_UNKNOWN</code>	Backend type is unknown.
<code>BACKEND_TYPE_RW</code>	Backend is available for read/write.
<code>BACKEND_TYPE_RO</code>	Backend is available only for read-only use.

### Server Command Constants

The following values are used in the packets exchanged between the client and server to identify the information in the rest of the packet. These items are entries within the main `proxy` table. The packet type is defined as the first character in the sent packet. For example, when intercepting packets from the client to edit or monitor a query you would check that the first byte of the packet was of type `proxy.COM_QUERY`.

Constant	Description
<code>COM_SLEEP</code>	Sleep
<code>COM_QUIT</code>	Quit
<code>COM_INIT_DB</code>	Initialize database
<code>COM_QUERY</code>	Query
<code>COM_FIELD_LIST</code>	Field List
<code>COM_CREATE_DB</code>	Create database
<code>COM_DROP_DB</code>	Drop database
<code>COM_REFRESH</code>	Refresh
<code>COM_SHUTDOWN</code>	Shutdown
<code>COM_STATISTICS</code>	Statistics
<code>COM_PROCESS_INFO</code>	Process List
<code>COM_CONNECT</code>	Connect
<code>COM_PROCESS_KILL</code>	Kill
<code>COM_DEBUG</code>	Debug
<code>COM_PING</code>	Ping
<code>COM_TIME</code>	Time
<code>COM_DELAYED_INSERT</code>	Delayed insert
<code>COM_CHANGE_USER</code>	Change user
<code>COM_BINLOG_DUMP</code>	Binlog dump
<code>COM_TABLE_DUMP</code>	Table dump
<code>COM_CONNECT_OUT</code>	Connect out
<code>COM_REGISTER_SLAVE</code>	Register slave
<code>COM_STMT_PREPARE</code>	Prepare server-side statement
<code>COM_STMT_EXECUTE</code>	Execute server-side statement
<code>COM_STMT_SEND_LONG_DATA</code>	Long data
<code>COM_STMT_CLOSE</code>	Close server-side statement
<code>COM_STMT_RESET</code>	Reset statement
<code>COM_SET_OPTION</code>	Set option
<code>COM_STMT_FETCH</code>	Fetch statement
<code>COM_DAEMON</code>	Daemon (MySQL 5.1 only)
<code>COM_ERROR</code>	Error

### MySQL Type Constants

These constants are used to identify the field types in the query result data returned to clients from the result of a query. These items are entries within the main `proxy` table.

Constant	Field Type
<code>MYSQL_TYPE_DECIMAL</code>	Decimal
<code>MYSQL_TYPE_NEWDECIMAL</code>	Decimal (MySQL 5.0 or later)
<code>MYSQL_TYPE_TINY</code>	Tiny
<code>MYSQL_TYPE_SHORT</code>	Short
<code>MYSQL_TYPE_LONG</code>	Long
<code>MYSQL_TYPE_FLOAT</code>	Float

Constant	Field Type
<code>MYSQL_TYPE_DOUBLE</code>	Double
<code>MYSQL_TYPE_NULL</code>	Null
<code>MYSQL_TYPE_TIMESTAMP</code>	Timestamp
<code>MYSQL_TYPE_LONGLONG</code>	Long long
<code>MYSQL_TYPE_INT24</code>	Integer
<code>MYSQL_TYPE_DATE</code>	Date
<code>MYSQL_TYPE_TIME</code>	Time
<code>MYSQL_TYPE_DATETIME</code>	Datetime
<code>MYSQL_TYPE_YEAR</code>	Year
<code>MYSQL_TYPE_NEWDATE</code>	Date (MySQL 5.0 or later)
<code>MYSQL_TYPE_ENUM</code>	Enumeration
<code>MYSQL_TYPE_SET</code>	Set
<code>MYSQL_TYPE_TINY_BLOB</code>	Tiny Blob
<code>MYSQL_TYPE_MEDIUM_BLOB</code>	Medium Blob
<code>MYSQL_TYPE_LONG_BLOB</code>	Long Blob
<code>MYSQL_TYPE_BLOB</code>	Blob
<code>MYSQL_TYPE_VAR_STRING</code>	Varstring
<code>MYSQL_TYPE_STRING</code>	String
<code>MYSQL_TYPE_TINY</code>	Tiny (compatible with <code>MYSQL_TYPE_CHAR</code> )
<code>MYSQL_TYPE_ENUM</code>	Enumeration (compatible with <code>MYSQL_TYPE_INTERVAL</code> )
<code>MYSQL_TYPE_GEOMETRY</code>	Geometry
<code>MYSQL_TYPE_BIT</code>	Bit

### 30.4.3. Capturing a connection with `connect_server()`

When the proxy accepts a connection from a MySQL client, the `connect_server()` function is called.

There are no arguments to the function, but you can use and if necessary manipulate the information in the `proxy.connection` table, which is unique to each client session.

For example, if you have multiple backend servers then you can set the server to be used by that connection by setting the value of `proxy.connection.backend_ndx` to a valid server number. The code below will choose between two servers based on whether the current time in minutes is odd or even:

```
function connect_server()
 print("--> a client really wants to talk to a server")
 if (tonumber(os.date("%M")) % 2 == 0) then
 proxy.connection.backend_ndx = 2
 print("Choosing backend 2")
 else
 proxy.connection.backend_ndx = 1
 print("Choosing backend 1")
 end
 print("Using " .. proxy.backends[proxy.connection.backend_ndx].address)
end
```

In this example the IP address/port combination is also displayed by accessing the information from the internal `proxy.backends` table.

### 30.4.4. Examining the handshake with `read_handshake()`

Handshake information is sent by the server to the client after the initial connection (through `connect_server()`) has been made. The handshake information contains details about the MySQL version, the ID of the thread that will handle the connection information, and the IP address of the client and server. This information is exposed through a Lua table as the only argument to the function.

- `mysqld_version` — the version of the MySQL server.

- `thread_id` — the thread ID.
- `scramble` — the password scramble buffer.
- `server_addr` — the IP address of the server.
- `client_addr` — the IP address of the client.

For example, you can print out the handshake data and refuse clients by IP address with the following function:

```
function read_handshake(auth)
 print("<-- let's send him some information about us")
 print(" mysql-version: " .. auth.mysql_version)
 print(" thread-id : " .. auth.thread_id)
 print(" scramble-buf : " .. string.format("%q", auth.scramble))
 print(" server-addr : " .. auth.server_addr)
 print(" client-addr : " .. auth.client_addr)

 if not auth.client_addr:match("^127.0.0.1:") then
 proxy.response.type = proxy.MYSQLD_PACKET_ERR
 proxy.response.errmsg = "only local connects are allowed"

 print("we don't like this client");

 return proxy.PROXY_SEND_RESULT
 end
end
```

Note that you have to return an error packet to the client by using `proxy.PROXY_SEND_RESULT`.

### 30.4.5. Examining the authentication credentials with `read_auth()`

The `read_auth()` function is triggered when an authentication handshake is initiated by the client. In the execution sequence, `read_auth()` occurs immediately after `read_handshake()`, so the server selection has already been made, but the connection and authorization information has not yet been provided to the backend server.

The function accepts a single argument, an Lua table containing the authorization information for the handshake process. The entries in the table are:

- `username` — the user login for connecting to the server.
- `password` — the password, encrypted, to be used when connecting.
- `default_db` — the default database to be used once the connection has been made.

For example, you can print the username and password supplied during authorization using:

```
function read_auth(auth)
 print(" username : " .. auth.username)
 print(" password : " .. string.format("%q", auth.password))
end
```

You can interrupt the authentication process within this function and return an error packet back to the client by constructing a new packet and returning `proxy.PROXY_SEND_RESULT`:

```
proxy.response.type = proxy.MYSQLD_PACKET_ERR
proxy.response.errmsg = "Logins are not allowed"
return proxy.PROXY_SEND_RESULT
```

### 30.4.6. Accessing authentication information with `read_auth_result()`

The return packet from the server during authentication is captured by `read_auth_result()`. The only argument to this function is the authentication packet returned by the server. As the packet is a raw MySQL network protocol packet, you must access the first byte to identify the packet type and contents. The `MYSQLD_PACKET_ERR` and `MYSQLD_PACKET_OK` constants can be used to identify whether the authentication was successful:

```
function read_auth_result(auth)
 local state = auth.packet:byte()

 if state == proxy.MYSQLD_PACKET_OK then
 print("<-- auth ok");
 elseif state == proxy.MYSQLD_PACKET_ERR then
 print("<-- auth failed");
 else
 end
end
```

```

 print("<-- auth ... don't know: " .. string.format("%q", auth.packet));
 end
end

```

### 30.4.7. Manipulating Queries with `read_query()`

The `read_query()` function is called once for each query submitted by the client and accepts a single argument, the query packet that was provided. To access the content of the packet you must parse the packet contents manually.

For example, you can intercept a query packet and print out the contents using the following function definition:

```

function read_query(packet)
 if packet:byte() == proxy.COM_QUERY then
 print("we got a normal query: " .. packet:sub(2))
 end
end
end

```

This example checks the first byte of the packet to determine the type. If the type is `COM_QUERY` (see [Section 30.4.2, “Internal Structures” \[1812\]](#)), then we extract the query from the packet and print it out. The structure of the packet type supplied is important. In the case of a `COM_QUERY` packet, the remaining contents of the packet are the text of the query string. In this example, no changes have been made to the query or the list of queries that will ultimately be sent to the MySQL server.

To modify a query, or add new queries, you must populate the query queue (`proxy.queries`) and then execute the queries that you have placed into the queue. If you do not modify the original query or the queue, then the query received from the client is sent to the MySQL server verbatim.

When adding queries to the queue, you should follow these guidelines:

- The packets inserted into the queue must be valid query packets. For each packet, you must set the initial byte to the packet type. If you are appending a query, you can append the query statement to the rest of the packet.
- Once you add a query to the queue, the queue is used as the source for queries sent to the server. If you add a query to the queue to add more information, you must also add the original query to the queue or it will not be executed.
- Once the queue has been populated, you must set the return value from `read_query()` to indicate whether the query queue should be sent to the server.
- When you add queries to the queue, you should add an ID. The ID you specify is returned with the result set so that you identify each query and corresponding result set. The ID has no other purpose than as an identifier for correlating the query and result set. When operating in a passive mode, during profiling for example, you want to identify the original query and the corresponding resultset so that the results expect by the client can be returned correctly.
- Unless your client is designed to cope with more result sets than queries, you should ensure that the number of queries from the client match the number of results sets returned to the client. Using the unique ID and removing result sets you inserted will help.

Normally, the `read_query()` and `read_query_result()` function are used in conjunction with each other to inject additional queries and remove the additional result sets. However, `read_query_result()` is only called if you populate the query queue within `read_query()`.

### 30.4.8. Manipulating Results with `read_query_result()`

The `read_query_result()` is called for each result set returned by the server only if you have manually injected queries into the query queue. If you have not manipulated the query queue then this function is not called. The function supports a single argument, the result packet, which provides a number of properties:

- `id` — the ID of the result set, which corresponds to the ID that was set when the query packet was submitted to the server when using `append(id)` on the query queue.
- `query` — the text of the original query.
- `query_time` — the number of microseconds required to receive the first row of a result set.
- `response_time` — the number of microseconds required to receive the last row of the result set.
- `resultset` — the content of the result set data.

By accessing the result information from the MySQL server you can extract the results that match the queries that you injected, return different result sets (for example, from a modified query), and even create your own result sets.

The Lua script below, for example, will output the query, followed by the query time and response time (i.e. the time to execute the query and the time to return the data for the query) for each query sent to the server:

```
function read_query(packet)
 if packet:byte() == proxy.COM_QUERY then
 print("we got a normal query: " .. packet:sub(2))

 proxy.queries:append(1, packet)

 return proxy.PROXY_SEND_QUERY
 end
end

function read_query_result(inj)
 print("query-time: " .. (inj.query_time / 1000) .. "ms")
 print("response-time: " .. (inj.response_time / 1000) .. "ms")
end
```

You can access the rows of returned results from the resultset by accessing the rows property of the resultset property of the result that is exposed through `read_query_result()`. For example, you can iterate over the results showing the first column from each row using this Lua fragment:

```
for row in inj.resultset.rows do
 print("injected query returned: " .. row[1])
end
```

Just like `read_query()`, `read_query_result()` can return different values for each result according to the result returned. If you have injected additional queries into the query queue, for example, then you will want to remove the results returned from those additional queries and only return the results from the query originally submitted by the client.

The example below injects additional `SELECT NOW()` statements into the query queue, giving them a different ID to the ID of the original query. Within `read_query_result()`, if the ID for the injected queries is identified, we display the result row, and return the `proxy.PROXY_IGNORE_RESULT` from the function so that the result is not returned to the client. If the result is from any other query, we print out the query time information for the query and return the default, which passes on the result set unchanged. We could also have explicitly returned `proxy.PROXY_IGNORE_RESULT` to the MySQL client.

```
function read_query(packet)
 if packet:byte() == proxy.COM_QUERY then
 proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()")
 proxy.queries:append(1, packet)
 proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()")

 return proxy.PROXY_SEND_QUERY
 end
end

function read_query_result(inj)
 if inj.id == 2 then
 for row in inj.resultset.rows do
 print("injected query returned: " .. row[1])
 end
 return proxy.PROXY_IGNORE_RESULT
 else
 print("query-time: " .. (inj.query_time / 1000) .. "ms")
 print("response-time: " .. (inj.response_time / 1000) .. "ms")
 end
end
```

For further examples, see [Section 30.5, “Using MySQL Proxy”](#).

## 30.5. Using MySQL Proxy

There are a number of different ways to use MySQL Proxy. At the most basic level, you can allow MySQL Proxy to pass on queries from clients to a single server. To use MySQL proxy in this mode, you just have to specify the backend server that the proxy should connect to on the command line:

```
$ mysql-proxy --proxy-backend-addresses=sakila:3306
```

If you specify multiple backend MySQL servers then the proxy will connect each client to each server in a round-robin fashion. For example, imagine you have two MySQL servers, A and B. The first client to connect will be connected to server A, the second to server B, the third to server C. For example:

```
$ mysql-proxy \
 --proxy-backend-addresses=narcissus:3306 \
 --proxy-backend-addresses=nostromo:3306
```

When you have specified multiple servers in this way, the proxy will automatically identify when a MySQL server has become unavailable and mark it accordingly. New connections will automatically be attached to a server that is available, and a warning will be reported to the standard output from `mysql-proxy`:

```
network-mysqld.c.367: connect(nostromo:3306) failed: Connection refused
network-mysqld-proxy.c.2405: connecting to backend (nostromo:3306) failed, marking it as down for ...
```

Lua scripts enable a finer level of control, both over the connections and their distribution and how queries and result sets are processed. When using an Lua script, you must specify the name of the script on the command line using the `-proxy-lua-script` option:

```
$ mysql-proxy --proxy-lua-script=mc.lua --proxy-backend-addresses=sakila:3306
```

When you specify a script, the script is not executed until a connection is made. This means that faults with the script will not be raised until the script is executed. Script faults will not affect the distribution of queries to backend MySQL servers.

### Note

Because the script is not read until the connection is made, you can modify the contents of the Lua script file while the proxy is still running and the script will automatically be used for the next connection. This ensures that MySQL Proxy remains available because it does not have to be restarted for the changes to take effect.

## 30.5.1. Using the Administration Interface

The `mysql-proxy` administration interface can be accessed using any MySQL client using the standard protocols. You can use the administration interface to gain information about the proxy server as a whole - standard connections to the proxy are isolated to operate as if you were connected directly to the backend MySQL server. Currently, the interface supports a limited set of functionality designed to provide connection and configuration information.

Because connectivity is provided over the standard MySQL protocol, you must access this information using SQL syntax. By default, the administration port is configured as 4041. You can change this port number using the `--admin-address` command-line option.

To get a list of the currently active connections to the proxy:

```
mysql> select * from proxy_connections;
+----+-----+-----+-----+
| id | type | state | db |
+----+-----+-----+-----+
| 0 | server | 0 | |
| 1 | proxy | 0 | |
| 2 | server | 10 | |
+----+-----+-----+-----+
3 rows in set (0.00 sec)
```

To get the current configuration:

```
mysql> select * from proxy_config;
+-----+-----+
| option | value |
+-----+-----+
| admin.address | :4041 |
| proxy.address | :4040 |
| proxy.lua_script | mc.lua |
| proxy.backend_addresses[0] | mysql:3306 |
| proxy.fix_bug_25371 | 0 |
| proxy.profiling | 1 |
+-----+-----+
6 rows in set (0.01 sec)
```

---

# Chapter 31. Extending MySQL

## 31.1. MySQL Internals

This chapter describes a lot of things that you need to know when working on the MySQL code. If you plan to contribute to MySQL development, want to have access to the bleeding-edge versions of the code, or just want to keep track of development, follow the instructions in [Section 2.9.3, “Installing from the Development Source Tree”](#). If you are interested in MySQL internals, you should also subscribe to our `internals` mailing list. This list has relatively low traffic. For details on how to subscribe, please see [Section 1.6.1, “MySQL Mailing Lists”](#). All developers at MySQL AB are on the `internals` list and we help other people who are working on the MySQL code. Feel free to use this list both to ask questions about the code and to send patches that you would like to contribute to the MySQL project!

### 31.1.1. MySQL Threads

The MySQL server creates the following threads:

- Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.
- Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

For information about tuning the parameters that control thread resources, see [Section 7.5.7, “How MySQL Uses Threads for Client Connections”](#).

- On a master replication server, connections from slave servers are handled like client connections: There is one thread per connected slave.
- On a slave replication server, an I/O thread is started to connect to the master server and read updates from it. An SQL thread is started to apply updates read from the master. These two threads run independently and can be started and stopped independently.
- A signal thread handles all signals. This thread also normally handles alarms and calls `process_alarm()` to force timeouts on connections that have been idle too long.
- If `InnoDB` is used, there will be 4 additional threads by default. Those are file I/O threads, controlled by the `innodb_file_io_threads` parameter. See [Section 13.5.4, “InnoDB Startup Options and System Variables”](#).
- If `mysqld` is compiled with `-DUSE_ALARM_THREAD`, a dedicated thread that handles alarms is created. This is only used on some systems where there are problems with `sigwait()` or if you want to use the `thr_alarm()` code in your application without a dedicated signal handling thread.
- If the server is started with the `--flush_time=val` option, a dedicated thread is created to flush all tables every `val` seconds.
- Each table for which `INSERT DELAYED` statements are issued gets its own thread. See [Section 12.2.4.2, “INSERT DELAYED Syntax”](#).
- If the event scheduler is active, there is one thread for the scheduler, and a thread for each event currently running. See [Section 24.1, “Event Scheduler Overview”](#).

`mysqladmin processlist` only shows the connection, `INSERT DELAYED`, replication, and event threads.

#### MySQL Enterprise

For expert advice on thread management subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

### 31.1.2. MySQL Test Suite

The test system that is included in Unix source and binary distributions makes it possible for users and developers to perform regression tests on the MySQL code. These tests can be run on Unix.

The current set of test cases doesn't test everything in MySQL, but it should catch most obvious bugs in the SQL processing code, operating system or library issues, and is quite thorough in testing replication. Our goal is to have the tests cover 100% of the code. We welcome contributions to our test suite. You may especially want to contribute tests that examine the functionality critical to your system because this ensures that all future MySQL releases work well with your applications.

The test system consists of a test language interpreter (`mysqltest`), a Perl script to run all tests (`mysql-test-run.pl`), the actual test cases written in a special test language, and their expected results. To run the test suite on your system after a build, type `make test` from the source root directory, or change location to the `mysql-test` directory and type `./mysql-test-run.pl`. If you have installed a binary distribution, change location to the `mysql-test` directory under the installation root directory (for example, `/usr/local/mysql/mysql-test`), and run `./mysql-test-run.pl`. All tests should succeed. If any do not, feel free to try to find out why and report the problem if it indicates a bug in MySQL. See [Section 1.7, “How to Report Bugs or Problems”](#).

If one test fails, you should run `mysql-test-run.pl` with the `--force` option to check whether any other tests fail.

If you have a copy of `mysqld` running on the machine where you want to run the test suite, you do not have to stop it, as long as it is not using ports `9306` or `9307`. If either of those ports is taken, you should set the `MTR_BUILD_THREAD` environment variable to an appropriate value, and the test suite will use a different set of ports for master, slave, NDB, and Instance Manager). For example:

```
shell> export MTR_BUILD_THREAD=31
shell> ./mysql-test-run.pl [options] [test_name]
```

In the `mysql-test` directory, you can run an individual test case with `./mysql-test-run.pl test_name`.

You can use the `mysqltest` language to write your own test cases. This is documented in the MySQL Test Framework manual, available at <http://dev.mysql.com/doc/>.

If you have a question about the test suite, or have a test case to contribute, send an email message to the MySQL [internals](#) mailing list. See [Section 1.6.1, “MySQL Mailing Lists”](#). This list does not accept attachments, so you should FTP all the relevant files to: <ftp://ftp.mysql.com/pub/mysql/upload/>

## 31.2. The MySQL Plugin Interface

MySQL 5.1 and up supports a plugin API that allows the loading and unloading of server components at runtime, without restarting the server. Currently, the plugin API supports creation of full-text parser plugins. Such a plugin can be used to replace or augment the built-in full-text parser. For example, a plugin can parse text into words using rules that differ from those used by the built-in parser. This can be useful if you need to parse text with characteristics different from those expected by the built-in parser.

The plugin interface is intended as the successor to the older user-defined function (UDF) interface. The plugin interface eventually will include an API for creating UDFs, and it is intended this plugin UDF API will replace the older non-plugin UDF API. After that point, it will be possible for UDFs to be revised for use as plugin UDFs so that they can take advantage of the better security and versioning capabilities of the plugin API. Eventually, support for the older UDF API will be phased out.

The plugin interface requires the `plugin` table in the `mysql` database. This table is created as part of the MySQL installation process. If you are upgrading from an older version to MySQL 5.1, you should run the `mysql_upgrade` command to create this table. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

### 31.2.1. Characteristics of the Plugin Interface

In some respects, the plugin API is similar to the older user-defined function (UDF) API that it supersedes, but the plugin API has several advantages over the older interface:

- The plugin framework is extendable to accommodate different kinds of plugins.

Some aspects of the plugin API are common to all types of plugins, but the API also allows for type-specific interface elements so that different types of plugins can be created. A plugin with one purpose can have an interface most appropriate to its own requirements and not the requirements of some other plugin type.

Although only the interface for full-text parser plugins is implemented currently, others can be added, such as an interface for UDF plugins.

- The plugin API includes versioning information.

The version information included in the plugin API enables a plugin library and each plugin that it contains to be self-identifying with respect to the API version that was used to build the library. If the API changes over time, the version numbers will change, but a server can examine a given plugin library's version information to determine whether it supports the plugins in the library.

There are two types of version numbers. The first is the version for the general plugin framework itself. Each plugin library includes this kind of version number. The second type of version applies to individual plugins. Each specific type of plugin has a version for its interface, so each plugin in a library has a type-specific version number. For example, library containing a full-text parsing plugin has a general plugin API version number, and the plugin has a version number specific to the full-text plugin interface.

- Plugin security is improved relative to the UDF interface.

The older interface for writing non-plugin UDFs allowed libraries to be loaded from any directory searched by the system's dynamic linker, and the symbols that identified the UDF library were relatively non-specific. The newer rules are more strict. A plugin library must be installed in a specific dedicated directory for which the location is controlled by the server and cannot be changed at runtime. Also, the library must contain specific symbols that identify it as a plugin library. The server will not load something as a plugin if it was not built as a plugin.

The newer plugin interface eliminates the security issues of the older UDF interface. When a UDF plugin type is implemented, that will allow non-plugin UDFs to be brought into the plugin framework and the older interface to be phased out.

The plugin implementation includes the following components:

Source files (the locations given indicate where the files are found in a MySQL source distribution):

- `include/mysql/plugin.h` exposes the public plugin API. This file should be examined by anyone who wants to write a plugin library.
- `sql/sql_plugin.h` and `sql/sql_plugin.cc` comprise the internal plugin implementation. These files need not be consulted by plugin writers. They may be of interest for those who want to know more about how the server handles plugins.

System table:

- The `plugin` table in the `mysql` database lists each installed plugin and is required for plugin use. For new MySQL installations, this table is created during the installation process. If you are upgrading from a version older than MySQL 5.1, you should run `mysql_upgrade` to update your system tables and create the `plugin` table (see [Section 4.4.8](#), “`mysql_upgrade` — Check Tables for MySQL Upgrade”).

SQL statements:

- `INSTALL PLUGIN` registers a plugin in the `plugin` table and loads the plugin code.
- `UNINSTALL PLUGIN` unregisters a plugin from the `plugin` table and unloads the plugin code.
- The `WITH PARSER` clause for full-text index creation associates a full-text parser plugin with a given `FULLTEXT` index.
- `SHOW PLUGINS` displays information about known plugins. The `PLUGINS` table in `INFORMATION_SCHEMA` also contains plugin information.

System variable:

- `plugin_dir` indicates the location of the directory where all plugins must be installed. The value of this variable can be specified at server startup with a `--plugin_dir=path` option. As of MySQL 6.0.5, `mysql_config --plugindir` displays the default plugin directory pathname.

## 31.2.2. Full-Text Parser Plugins

MySQL has a built-in parser that it uses by default for full-text operations (parsing text to be indexed, or parsing a query string to determine the terms to be used for a search). For full-text processing, “parsing” means extracting words from text or a query string based on rules that define which character sequences make up a word and where word boundaries lie.

When parsing for indexing purposes, the parser passes each word to the server, which adds it to a full-text index. When parsing a query string, the parser passes each word to the server, which accumulates the words for use in a search.

The parsing properties of the built-in full-text parser are described in [Section 11.8](#), “Full-Text Search Functions”. These properties

include rules for determining how to extract words from text. The parser is influenced by certain system variables such as `ft_min_word_len` and `ft_max_word_len` that cause words shorter or longer to be excluded, and by the stopword list that identifies common words to be ignored.

The plugin API enables you to provide a full-text parser of your own so that you have control over the basic duties of a parser. A parser plugin can operate in either of two roles:

- The plugin can replace the built-in parser. In this role, the plugin reads the input to be parsed, splits it up into words, and passes the words to the server (either for indexing or for word accumulation).

One reason to use a parser this way is that you need to use different rules from those of the built-in parser for determining how to split up input into words. For example, the built-in parser considers the text “case-sensitive” to consist of two words “case” and “sensitive,” whereas an application might need to treat the text as a single word.

- The plugin can act in conjunction with the built-in parser by serving as a front end for it. In this role, the plugin extracts text from the input and passes the text to the parser, which splits up the text into words using its normal parsing rules. In particular, this parsing will be affected by the `ft_***` system variables and the stopword list.

One reason to use a parser this way is that you need to index content such as PDF documents, XML documents, or `.doc` files. The built-in parser is not intended for those types of input but a plugin can pull out the text from these input sources and pass it to the built-in parser.

It is also possible for a parser plugin to operate in both roles. That is, it could extract text from non-plaintext input (the front end role), and also parse the text into words (thus replacing the built-in parser).

A full-text plugin is associated with full-text indexes on a per-index basis. That is, when you install a parser plugin initially, that does not cause it to be used for any full-text operations. It simply becomes available. For example, a full-text parser plugin becomes available to be named in a `WITH PARSE` clause when creating individual `FULLTEXT` indexes. To create such an index at table-creation time, do this:

```
CREATE TABLE t
(
 doc CHAR(255),
 FULLTEXT INDEX (doc) WITH PARSE my_parser
);
```

Or you can add the index after the table has been created:

```
ALTER TABLE t ADD FULLTEXT INDEX (doc) WITH PARSE my_parser;
```

The only SQL change for associating the parser with the index is the `WITH PARSE` clause. Searches are specified as before, with no changes needed for queries.

When you associate a parser plugin with a `FULLTEXT` index, the plugin is required for using the index. If the parser plugin is dropped, any index associated with it becomes unusable. Any attempt to use it a table for which a plugin is not available results in an error, although `DROP TABLE` is still possible.

### 31.2.3. INSTALL PLUGIN Syntax

```
INSTALL PLUGIN plugin_name SONAME 'plugin_library'
```

This statement installs a plugin.

*plugin\_name* is the name of the plugin as defined in the plugin declaration structure contained in the library file. Plugin name case sensitivity is determined by the host system filename semantics.

*plugin\_library* is the name of the shared library that contains the plugin code. The name includes the filename extension (for example, `libmyplugin.so` or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (that is, the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is `plugin` directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative pathname, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` adds a line to the `mysql.plugin` table that describes the `plugin`. This table contains the plugin name and library filename.

`INSTALL PLUGIN` also loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used.

To use `INSTALL PLUGIN`, you must have the `INSERT privilege` for the `mysql.plugin` table.

At server startup, the server loads and initializes any plugin that is listed in the `mysql.plugin` table. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

To remove a plugin entirely, use the `UNINSTALL PLUGIN` statement:

To see what plugins are installed, use the `SHOW PLUGIN` statement.

If you recompile a plugin library and need to reinstall it, you can use either of the following procedures:

- Use `UNINSTALL PLUGIN` to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use `INSTALL PLUGIN` to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.
- Alternatively, stop the server, install the new plugin library file in the plugin directory, and then restart the server.

## 31.2.4. UNINSTALL PLUGIN Syntax

```
UNINSTALL PLUGIN plugin_name
```

This statement removes an installed plugin. You cannot uninstall a plugin if any table that uses it is open.

`plugin_name` must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` table, so that subsequent server restarts will not load and initialize the plugin. `UNINSTALL PLUGIN` does not remove the plugin's shared library file.

To use `UNINSTALL PLUGIN`, you must have the `DELETE` privilege for the `mysql.plugin` table.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a `FULLTEXT` index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the `WITH PARSER` clause from the dumped `CREATE TABLE` statement so that you can reload the table later. If you do not care about the table, `DROP TABLE` can be used even if any plugins associated with the table are missing.

## 31.2.5. Writing Plugins

This section describes the general and type-specific parts of the plugin API. It also provides a step-by-step guide to creating a plugin library. For example plugin source code, see the `plugin/fulltext` directory of a MySQL source distribution.

You can write plugins in C or C++ (or another language that can use C calling conventions). Plugins are loaded and unloaded dynamically, so your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

A plugin contains code that becomes part of the running server, so when you write a plugin, you are bound by any and all constraints that otherwise apply to writing server code. For example, you may have problems if you attempt to use functions from the `libstdc++` library. These constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to plugins that were originally written for older servers. For information about these constraints, see [Section 2.9.2, "Typical configure Options"](#), and [Section 2.9.4, "Dealing with Problems Compiling MySQL"](#).

### 31.2.5.1. General Plugin Structures and Functions

Every plugin must have a general plugin declaration. The declaration corresponds to the `st_mysql_plugin` structure in the `plugin.h` file:

```

struct st_mysql_plugin
{
 int type; /* the plugin type (a MYSQL_XXX_PLUGIN value) */
 void *info; /* pointer to type-specific plugin descriptor */
 const char *name; /* plugin name */
 const char *author; /* plugin author (for SHOW PLUGINS) */
 const char *descr; /* general descriptive text (for SHOW PLUGINS) */
 int license; /* the plugin license (PLUGIN_LICENSE_XXX) */
 int (*init)(void *); /* the function to invoke when plugin is loaded */
 int (*deinit)(void *); /* the function to invoke when plugin is unloaded */
 unsigned int version; /* plugin version (for SHOW PLUGINS) */
 struct st_mysql_show_var *status_vars;
 void * __reserved1; /* placeholder for system variables */
 void * __reserved2; /* placeholder for config options */
};

```

The `st_mysql_plugin` structure is common to every type of plugin. Its members should be filled in as follows:

- `type`

The plugin type. This must be one of the plugin-type values from `plugin.h`. For a full-text parser plugin, the `type` value is `MYSQL_FTPARSER_PLUGIN`.

- `info`

A pointer to the descriptor for the plugin. Unlike the general plugin declaration structure, this descriptor's structure depends on the particular type of plugin. Each descriptor has a version number that indicates the API version for that type of plugin, plus any other members needed. The descriptor for full-text plugins is described in [Section 31.2.5.2, “Type-Specific Plugin Structures and Functions”](#).

- `name`

The plugin name. This is the name that will be listed in the `plugin` table and by which you refer to the plugin in SQL statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.

- `author`

The plugin author. This can be whatever you like.

- `desc`

A general description of the plugin. This can be whatever you like.

- `license`

The plugin license type. The value can be one of `PLUGIN_LICENSE_PROPRIETARY`, `PLUGIN_LICENSE_GPL`, or `PLUGIN_LICENSE_BSD`.

- `init`

A once-only initialization function. This is executed when the plugin is loaded, which happens for `INSTALL PLUGIN` or, for plugins listed in the `plugin` table, at server startup. The function takes no arguments. It returns zero for success and non-zero for failure. If an `init` function is unneeded for a plugin, it can be specified as 0.

- `deinit`

A once-only deinitialization function. This is executed when the plugin is unloaded, which happens for `UNINSTALL PLUGIN` or, for plugins listed in the `plugin` table, at server shutdown. The function takes no arguments. It returns zero for success and non-zero for failure. If a `deinit` function is unneeded for a plugin, it can be specified as 0.

- `version`

The plugin version number. When the plugin is installed, this value can be retrieved from the `INFORMATION_SCHEMA.PLUGINS` table. The value includes major and minor numbers. If you write the value as a hex constant, the format is `0xMMNN`, where `MM` and `NN` are the major and minor numbers, respectively. For example, `0x0302` represents version 3.2.

- `status_vars`

A pointer to a structure for status variables associated with the plugin, or 0 if there are no such variables. When the plugin is installed, these variables are displayed in the output of the `SHOW STATUS` statement.

- `__reserved1`, `__reserved2`

These are placeholders for the future. Currently, they should be set to `NULL`.

The `init` and `deinit` functions in the general plugin declaration are invoked only when loading and unloading the plugin. They have nothing to do with use of the plugin such as happens when an SQL statement causes the plugin to be invoked.

The `status_vars` member, if not 0, points to an array of `st_mysql_show_var` structures, each of which describes one status variable, followed by a structure with all members set to 0. The `st_mysql_show_var` structure has this definition:

```
struct st_mysql_show_var {
 const char *name;
 char *value;
 enum enum_mysql_show_type type;
};
```

When the plugin is installed, the plugin name and the `name` value are joined with an underscore to form the name displayed by `SHOW STATUS`.

The following table shows the allowable status variable `type` values and what the corresponding variable should be:

Type	Meaning
<code>SHOW_BOOL</code>	Pointer to a boolean variable
<code>SHOW_INT</code>	Pointer to an integer variable
<code>SHOW_LONG</code>	Pointer to a long integer variable
<code>SHOW_LONGLONG</code>	Pointer to a longlong integer variable
<code>SHOW_CHAR</code>	A string
<code>SHOW_CHAR_PTR</code>	Pointer to a string
<code>SHOW_ARRAY</code>	Pointer to another <code>st_mysql_show_var</code> array
<code>SHOW_FUNC</code>	Pointer to a function

For the `SHOW_FUNC` type, the function is called and fills in its `out` parameter, which then provides information about the variable to be displayed. The function has this signature:

```
#define SHOW_VAR_FUNC_BUFF_SIZE 1024
typedef int (*mysql_show_var_func) (void *thd,
 struct st_mysql_show_var *out,
 char *buf);
```

Plugins should consider the `thd` parameter to be read only.

### 31.2.5.2. Type-Specific Plugin Structures and Functions

In the `st_mysql_plugin` structure that defines a plugin's general declaration, the `info` member points to a type-specific plugin descriptor. For a full-text parser plugin, the descriptor corresponds to the `st_mysql_ftparser` structure in the `plugin.h` file:

```
struct st_mysql_ftparser
{
 int interface_version;
 int (*parse)(MYSQL_FTPARSER_PARAM *param);
 int (*init)(MYSQL_FTPARSER_PARAM *param);
 int (*deinit)(MYSQL_FTPARSER_PARAM *param);
};
```

As shown by the structure definition, the descriptor has a version number (`MYSQL_FTPARSER_INTERFACE_VERSION` for full-text parser plugins) and contains pointers to three functions. The `init` and `deinit` members should point to a function or be set to 0 if the function is not needed. The `parse` member must point to the function that performs the parsing.

A full-text parser plugin is used in two different contexts, indexing and searching. In both contexts, the server calls the initialization and deinitialization functions at the beginning and end of processing each SQL statement that causes the plugin to be invoked. However, during statement processing, the server calls the main parsing function in context-specific fashion:

- For indexing, the server calls the parser for each column value to be indexed.
- For searching, the server calls the parser to parse the search string. The parser might also be called for rows processed by the statement. In natural language mode, there is no need for the server to call the parser. For boolean mode phrase searches or nat-

ural language searches with query expansion, the parser is used to parse column values for information that is not in the index. Also, if a boolean mode search is done for a column that has no `FULLTEXT` index, the built-in parser will be called. (Plugins are associated with specific indexes. If there is no index, no plugin is used.)

Note that the plugin declaration in the plugin library descriptor has initialization and deinitialization functions, and so does the plugin descriptor to which it points. These pairs of functions have different purposes and are invoked for different reasons:

- For the plugin declaration in the plugin library descriptor, the initialization and deinitialization functions are invoked when the plugin is loaded and unloaded.
- For the plugin descriptor, the initialization and deinitialization functions are invoked per SQL statement for which the plugin is used.

Each interface function named in the plugin descriptor should return zero for success or non-zero for failure, and each of them receives an argument that points to a `MYSQL_FTPARSER_PARAM` structure containing the parsing context. The structure has this definition:

```
typedef struct st_mysql_ftparser_param
{
 int (*mysql_parse)(struct st_mysql_ftparser_param *,
 char *doc, int doc_len);
 int (*mysql_add_word)(struct st_mysql_ftparser_param *,
 char *word, int word_len,
 MYSQL_FTPARSER_BOOLEAN_INFO *boolean_info);
 void *ftparser_state;
 void *mysql_ftparam;
 struct charset_info_st *cs;
 char *doc;
 int length;
 int flags;
 enum enum_ftparser_mode mode;
} MYSQL_FTPARSER_PARAM;
```

### Note

The definition shown is current as of MySQL 5.1.12. It is incompatible with versions of MySQL 5.1 older than 5.1.12.

The structure members are used as follows:

- `mysql_parse`

A pointer to a callback function that invokes the server's built-in parser. Use this callback when the plugin acts as a front end to the built-in parser. That is, when the plugin parsing function is called, it should process the input to extract the text and pass the text to the `mysql_parse` callback.

The first parameter for this callback function should be the `param` value itself:

```
param->mysql_parse(param, ...);
```

A front end plugin can extract text and pass it all at once to the built-in parser, or it can extract and pass text to the built-in parser a piece at a time. However, in this case, the built-in parser treats the pieces of text as though there are implicit word breaks between them.

- `mysql_add_word`

A pointer to a callback function that adds a word to a full-text index or to the list of search terms. Use this callback when the parser plugin replaces the built-in parser. That is, when the plugin parsing function is called, it should parse the input into words and invoke the `mysql_add_word` callback for each word.

The first parameter for this callback function should be the `param` value itself:

```
param->mysql_add_word(param, ...);
```

- `ftparser_state`

This is a generic pointer. The plugin can set it to point to information to be used internally for its own purposes.

- `mysql_ftparam`

This is set by the server. It is passed as the first argument to the `mysql_parse` or `mysql_add_word` callback.

- `cs`

A pointer to information about the character set of the text, or 0 if no information is available.

- `doc`

A pointer to the text to be parsed.

- `length`

The length of the text to be parsed, in bytes.

- `flags`

Parser flags. This is zero if there are no special flags. Currently, the only non-zero flag is `MYSQL_FTFLAGS_NEED_COPY`, which means that `mysql_add_word()` must save a copy of the word (that is, it cannot use a pointer to the word because the word is in a buffer that will be overwritten.) This member was added in MySQL 5.1.12.

This flag might be set or reset by MySQL before calling the parser plugin, by the parser plugin itself, or by the `mysql_parse()` function.

- `mode`

The parsing mode. This value will be one of the following constants:

- `MYSQL_FTPARSER_SIMPLE_MODE`

Parse in fast and simple mode, which is used for indexing and for natural language queries. The parser should pass to the server only those words that should be indexed. If the parser uses length limits or a stopwords list to determine which words to ignore, it should not pass such words to the server.

- `MYSQL_FTPARSER_WITH_STOPWORDS`

Parse in stopwords mode. This is used in boolean searches for phrase matching. The parser should pass all words to the server, even stopwords or words that are outside any normal length limits.

- `MYSQL_FTPARSER_FULL_BOOLEAN_INFO`

Parse in boolean mode. This is used for parsing boolean query strings. The parser should recognize not only words but also boolean-mode operators and pass them to the server as tokens via the `mysql_add_word` callback. To tell the server what kind of token is being passed, the plugin needs to fill in a `MYSQL_FTPARSER_BOOLEAN_INFO` structure and pass a pointer to it.

If the parser is called in boolean mode, the `param->mode` value will be `MYSQL_FTPARSER_FULL_BOOLEAN_INFO`. The `MYSQL_FTPARSER_BOOLEAN_INFO` structure that the parser uses for passing token information to the server looks like this:

```
typedef struct st_mysql_ftparser_boolean_info
{
 enum enum_ft_token_type type;
 int yesno;
 int weight_adjust;
 bool wasign;
 bool trunc;
 /* These are parser state and must be removed. */
 byte prev;
 byte *quot;
} MYSQL_FTPARSER_BOOLEAN_INFO;
```

The parser should fill in the structure members as follows:

- `type`

The token type. This should be one of values shown in the following table:

Type	Meaning
<code>FT_TOKEN_EOF</code>	End of data
<code>FT_TOKEN_WORD</code>	A regular word

<code>FT_TOKEN_LEFT_PAREN</code>	The beginning of a group or subexpression
<code>FT_TOKEN_RIGHT_PAREN</code>	The end of a group or subexpression
<code>FT_TOKEN_STOPWORD</code>	A stopword

- `yesno`

Whether the word must be present for a match to occur. 0 means that the word is optional but increases the match relevance if it is present. Values larger than 0 mean that the word must be present. Values smaller than 0 mean that the word must not be present.

- `weight_adjust`

A weighting factor that determines how much a match for the word counts. It can be used to increase or decrease the word's importance in relevance calculations. A value of zero indicates no weight adjustment. Values greater than or less than zero mean higher or lower weight, respectively. The examples at [Section 11.8.2, “Boolean Full-Text Searches”](#), that use the `<` and `>` operators illustrate how weighting works.

- `wasign`

The sign of the weighting factor. A negative value acts like the `~` boolean-search operator, which causes the word's contribution to the relevance to be negative.

- `trunc`

Whether matching should be done as if the boolean-mode `*` truncation operator had been given.

Plugins should not use the `prev` and `quot` members of the `MYSQL_FTPARSER_BOOLEAN_INFO` structure.

### 31.2.5.3. Creating a Plugin Library

This section provides a step-by-step procedure for creating a plugin library. It shows how to develop a library that contains a full-text parsing plugin named `simple_parser`. This plugin performs parsing based on simpler rules than those used by the MySQL built-in full-text parser: Words are non-empty runs of whitespace characters.

Each plugin library has the following contents:

- A plugin library descriptor that indicates the version number of the general plugin API that the library uses and that contains a general declaration for each plugin in the library.
- Each plugin general declaration contains information that is common to all types of plugin: A value that indicates the plugin type; the plugin name, author, description, and license type; and pointers to the initialization and deinitialization functions that the server invokes when it loads and unloads the plugin.
- The plugin general declaration also contains a pointer to a type-specific plugin descriptor. The structure of these descriptors can vary from one plugin type to another, because each type of plugin can have its own API. A plugin descriptor contains a type-specific API version number and pointers to the functions that are needed to implement that plugin type. For example, a full-text parser plugin has initialization and deinitialization functions, and a main parsing function. The server invokes these functions when it uses the plugin to parse text.
- The plugin library contains the interface functions that are referenced by the library descriptor and by the plugin descriptors.

The easiest way to follow the instructions in this section is to use the source code in the `plugin/fulltext` directory of a MySQL source distribution. The instructions assume that you make a copy of that directory and use it to build the plugin library. To make a copy of the directory, use the following commands, which assume that the MySQL source tree is in a directory named `mysql-5.1` under your current directory:

```
shell> mkdir fulltext_plugin
shell> cp mysql-5.1/plugin/fulltext/* fulltext_plugin
```

After copying the source files, use the following procedure to create a plugin library:

1. Change location into the `fulltext_plugin` directory:

```
shell> cd fulltext_plugin
```

- The plugin source file should include the header files that the plugin library needs. The `plugin.h` file is required, and the library might require other files as well. For example:

```
#include <stdlib.h>
#include <ctype.h>
#include <mysql/plugin.h>
```

- Set up the plugin library file descriptor.

Every plugin library must include a library descriptor that must define two symbols:

- `_mysql_plugin_interface_version_` specifies the version number of the general plugin framework. This is given by the `MYSQL_PLUGIN_INTERFACE_VERSION` symbol, which is defined in the `plugin.h` file.
- `_mysql_plugin_declarations_` defines an array of plugin declarations, terminated by a declaration with all members set to 0. Each declaration is an instance of the `st_mysql_plugin` structure (also defined in `plugin.h`). There must be one of these for each plugin in the library.

If the server does not find these two symbols in a library, it does not accept it as a legal plugin library and rejects it with an error. This prevents use of a library for plugin purposes unless it was built specifically as a plugin library.

The standard (and most convenient) way to define the two required symbols is by using the `mysql_declare_plugin` and `mysql_declare_plugin_end` macros from the `plugin.h` file:

```
mysql_declare_plugin
... one or more plugin declarations here ...
mysql_declare_plugin_end;
```

For example, the library descriptor for a library that contains a single plugin named `simple_parser` looks like this:

```
mysql_declare_plugin
{
 MYSQL_FTPARSER_PLUGIN, /* type */
 &simple_parser_descriptor, /* descriptor */
 "simple_parser", /* name */
 "MySQL AB", /* author */
 "Simple Full-Text Parser", /* description */
 PLUGIN_LICENSE_GPL, /* plugin license */
 simple_parser_plugin_init, /* init function (when loaded) */
 simple_parser_plugin_deinit, /* deinit function (when unloaded) */
 0x0001, /* version */
 simple_status /* status variables */
}
mysql_declare_plugin_end;
```

For a full-text parser plugin, the type must be `MYSQL_FTPARSER_PLUGIN`. This is the value that identifies the plugin as being legal for use in a `WITH PARSER` clause when creating a `FULLTEXT` index. (No other plugin type is legal for this clause.)

The `mysql_declare_plugin` and `mysql_declare_plugin_end` macros are defined in `plugin.h` like this:

```
#ifndef MYSQL_DYNAMIC_PLUGIN
#define __MYSQL_DECLARE_PLUGIN(NAME, VERSION, PSIZE, DECLS) \
int VERSION= MYSQL_PLUGIN_INTERFACE_VERSION; \
int PSIZE= sizeof(struct st_mysql_plugin); \
struct st_mysql_plugin DECLS[]= {
#else
#define __MYSQL_DECLARE_PLUGIN(NAME, VERSION, PSIZE, DECLS) \
int _mysql_plugin_interface_version= MYSQL_PLUGIN_INTERFACE_VERSION; \
int _mysql_sizeof_struct_st_plugin= sizeof(struct st_mysql_plugin); \
struct st_mysql_plugin _mysql_plugin_declarations[]= {
#endif

#define mysql_declare_plugin(NAME) \
__MYSQL_DECLARE_PLUGIN(NAME, \
 builtin_ ## NAME ## _plugin_interface_version, \
 builtin_ ## NAME ## _sizeof_struct_st_plugin, \
 builtin_ ## NAME ## _plugin)

#define mysql_declare_plugin_end ,{0,0,0,0,0,0,0,0,0}
```

One point to note about those definitions is that the `_mysql_plugin_interface_version_` symbol is defined only if the `MYSQL_DYNAMIC_PLUGIN` symbol is defined. This means that you'll need to provide `-DMYSQL_DYNAMIC_PLUGIN` as part of the compilation command when you build the plugin.

When the macros are used as just shown, they expand to the following code, which defines both of the required symbols (`_mysql_plugin_interface_version_` and `_mysql_plugin_declarations_`):

```

int _mysql_plugin_interface_version = MYSQL_PLUGIN_INTERFACE_VERSION;
struct st_mysql_plugin _mysql_plugin_declarations[]= {
{
 MYSQL_FTPARSER_PLUGIN, /* type */
 &simple_parser_descriptor, /* descriptor */
 "simple_parser", /* name */
 "MySQL AB", /* author */
 "Simple Full-Text Parser", /* description */
 PLUGIN_LICENSE_GPL, /* plugin license */
 simple_parser_plugin_init, /* init function (when loaded) */
 simple_parser_plugin_deinit, /* deinit function (when unloaded) */
 0x0001, /* version */
 simple_status /* status variables */
}
, {0,0,0,0,0,0,0,0}
};

```

The preceding example declares a single plugin in the library descriptor, but it is possible to declare multiple plugins. List the declarations one after the other between `mysql_declare_plugin` and `mysql_declare_plugin_end`, separated by commas.

MySQL plugins can be written in C or C++ (or another language that can use C calling conventions). One feature of C++ is that you can use non-constant variables to initialize global structures. However, if you write a C++ plugin, you should not use this feature. Members of structures such as the `st_mysql_plugin` structure should be initialized with constant variables. See the discussion at the end of this section that describes some legal and illegal initializers for plugins.

#### 4. Set up the plugin descriptor.

Each plugin declaration in the library descriptor points to a type-specific descriptor for the corresponding plugin. In the `simple_parser` declaration, that descriptor is indicated by `&simple_parser_descriptor`. The descriptor specifies the version number for the full-text plugin interface (as given by `MYSQL_FTPARSER_INTERFACE_VERSION`), and the plugin's parsing, initialization, and deinitialization functions:

```

static struct st_mysql_ftparser simple_parser_descriptor=
{
 MYSQL_FTPARSER_INTERFACE_VERSION, /* interface version */
 simple_parser_parse, /* parsing function */
 simple_parser_init, /* parser init function */
 simple_parser_deinit /* parser deinit function */
};

```

#### 5. Set up the plugin interface functions.

The general plugin declaration in the library descriptor names the initialization and deinitialization functions that the server should invoke when it loads and unloads the plugin. For `simple_parser`, these functions do nothing but return zero to indicate that they succeeded:

```

static int simple_parser_plugin_init(void)
{
 return(0);
}

static int simple_parser_plugin_deinit(void)
{
 return(0);
}

```

Because those functions do not actually do anything, you could omit them and specify 0 for each of them in the plugin declaration.

The type-specific plugin descriptor for `simple_parser` names the initialization, deinitialization, and parsing functions that the server invokes when the plugin is used. For `simple_parser`, the initialization and deinitialization functions do nothing:

```

static int simple_parser_init(MYSQL_FTPARSER_PARAM *param)
{
 return(0);
}

static int simple_parser_deinit(MYSQL_FTPARSER_PARAM *param)
{
 return(0);
}

```

Here too, because those functions do nothing, you could omit them and specify 0 for each of them in the plugin descriptor.

The main parsing function, `simple_parser_parse()`, acts as a replacement for the built-in full-text parser, so it needs to split text into words and pass each word to the server. The parsing function's first argument is a pointer to a structure that contains the parsing context. This structure has a `doc` member that points to the text to be parsed, and a `length` member that in-

dicates how long the text is. The simple parsing done by the plugin considers non-empty runs of whitespace characters to be words, so it identifies words like this:

```
static int simple_parser_parse(MYSQL_FTPARSER_PARAM *param)
{
 char *end, *start, *docend= param->doc + param->length;

 for (end= start= param->doc;; end++)
 {
 if (end == docend)
 {
 if (end > start)
 add_word(param, start, end - start);
 break;
 }
 else if (isspace(*end))
 {
 if (end > start)
 add_word(param, start, end - start);
 start= end + 1;
 }
 }
 return(0);
}
```

As the parser finds each word, it invokes a function `add_word()` to pass the word to the server. `add_word()` is a helper function only; it is not part of the plugin interface. The parser passes the parsing context pointer to `add_word()`, as well as a pointer to the word and a length value:

```
static void add_word(MYSQL_FTPARSER_PARAM *param, char *word, size_t len)
{
 MYSQL_FTPARSER_BOOLEAN_INFO bool_info=
 { FT_TOKEN_WORD, 0, 0, 0, 0, ' ', 0 };
 param->mysql_add_word(param, word, len, &bool_info);
}
```

For boolean-mode parsing, `add_word()` fills in the members of the `bool_info` structure as described in [Section 31.2.5.2, “Type-Specific Plugin Structures and Functions”](#).

- Set up the status variables, if there are any. For the `simple_parser` plugin, the following status variable array sets up one status variable with a value that is static text, and another with a value that is stored in a long integer variable:

```
long number_of_calls= 0;
struct st_mysql_show_var simple_status[]=
{
 {"static", (char *)"just a static text", SHOW_CHAR},
 {"called", (char *)&number_of_calls, SHOW_LONG},
 {0,0,0}
};
```

When the plugin is installed, the plugin name and the `name` value are joined with an underscore to form the name displayed by `SHOW STATUS`. For the array just shown, the resulting status variable names are `simple_parser_static` and `simple_parser_called`. This convention means that you can easily display the variables for a plugin using its name:

```
mysql> SHOW STATUS LIKE 'simple_parser%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| simple_parser_static | just a static text |
| simple_parser_called | 0 |
+-----+-----+
```

- Compile the plugin library as a shared library and install it in the plugin directory.

### Note

As mentioned earlier, be sure to specify `-DMYSQL_DYNAMIC_PLUGIN` as part of the compilation command when you build the plugin.

The procedure for compiling shared objects varies from system to system. If you build your library using the GNU autotools, `libtool` should be able to generate the correct compilation commands for your system. If the library is named `mypluglib`, you should end up with a shared object file that has a name something like `libmypluglib.so`. (The file-name might have a different extension on your system.)

To use the autotools, you'll need to make a few changes to the configuration files at this point to enable the plugin to be compiled and installed. Assume that your MySQL distribution is installed at a base directory of `/usr/local/mysql` and that its header files are located in the `include` directory under the base directory.

Edit `Makefile.am`, which should look something like this:

```
#Makefile.am example for a plugin
pkglibdir=$(libdir)/mysql
INCLUDES= -I$(top_builddir)/include -I$(top_srcdir)/include
#noinst_LTLIBRARIES= mypluglib.la
pkglib_LTLIBRARIES= mypluglib.la
mypluglib_la_SOURCES= plugin_example.c
mypluglib_la_LDFLAGS= -module -rpath $(pkglibdir)
mypluglib_la_CFLAGS= -DMYSQL_DYNAMIC_PLUGIN
```

The `mypluglib_la_CFLAGS` line takes care of passing the `-DMYSQL_DYNAMIC_PLUGIN` flag to the compilation command.

Adjust the `INCLUDES` line to specify the pathname to the installed MySQL header files. Edit it to look like this:

```
INCLUDES= -I/usr/local/mysql/include
```

Make sure that the `noinst_LTLIBRARIES` line is commented out or remove it. Make sure that the `pkglib_LTLIBRARIES` line is not commented out; it enables the `make install` command.

Set up the files needed for the `configure` command, invoke it, and run `make`:

```
shell> autoreconf --force --install --symlink
shell> ./configure --prefix=/usr/local/mysql
shell> make
```

The `--prefix` option to `configure` indicates the MySQL base directory under which the plugin should be installed. You can see what value to use for this option with `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'basedir';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| base | /usr/local/mysql |
+-----+-----+
```

The location of the plugin directory where you should install the library is given by the `plugin_dir` system variable. For example:

```
mysql> SHOW VARIABLES LIKE 'plugin_dir';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| plugin_dir | /usr/local/mysql/lib/mysql/plugin |
+-----+-----+
```

To install the plugin library, use `make`:

```
shell> make install
```

Verify that `make install` installed the plugin library in the proper directory. After installing it, make sure that the library permissions allow it to be executed by the server.

8. Register the plugin with the server.

The `INSTALL PLUGIN` statement causes the server to list the plugin in the `plugin` table and to load the plugin code from the library file. Use that statement to register `simple_parser` with the server, and then verify that the plugin is listed in the `plugin` table:

```
mysql> INSTALL PLUGIN simple_parser SONAME 'libmypluglib.so';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM mysql.plugin;
+-----+-----+
| name | dl |
+-----+-----+
| simple_parser | libmypluglib.so |
+-----+-----+
1 row in set (0.00 sec)
```

9. Try the plugin.

Create a table that contains a string column and associate the parser plugin with a `FULLTEXT` index on the column:

```
mysql> CREATE TABLE t (c VARCHAR(255),
-> FULLTEXT (c) WITH PARSER simple_parser);
Query OK, 0 rows affected (0.01 sec)
```

Insert some text into the table and try some searches. These should verify that the parser plugin treats all non-whitespace characters as word characters:

```
mysql> INSERT INTO t VALUES
-> ('latin1_general_cs is a case-sensitive collation'),
-> ('I\'d like a case of oranges'),
-> ('this is sensitive information'),
-> ('another row'),
-> ('yet another row');
Query OK, 5 rows affected (0.02 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT c FROM t;
+-----+
| c |
+-----+
| latin1_general_cs is a case-sensitive collation |
| I'd like a case of oranges |
| this is sensitive information |
| another row |
| yet another row |
+-----+
5 rows in set (0.00 sec)
```

```
mysql> SELECT MATCH(c) AGAINST('case') FROM t;
+-----+
| MATCH(c) AGAINST('case') |
+-----+
| 0 |
| 1.2968142032623 |
| 0 |
| 0 |
| 0 |
+-----+
5 rows in set (0.00 sec)
```

```
mysql> SELECT MATCH(c) AGAINST('sensitive') FROM t;
+-----+
| MATCH(c) AGAINST('sensitive') |
+-----+
| 0 |
| 1.3253291845322 |
| 0 |
| 0 |
+-----+
5 rows in set (0.01 sec)
```

```
mysql> SELECT MATCH(c) AGAINST('case-sensitive') FROM t;
+-----+
| MATCH(c) AGAINST('case-sensitive') |
+-----+
| 1.3109166622162 |
| 0 |
| 0 |
| 0 |
| 0 |
+-----+
5 rows in set (0.01 sec)
```

```
mysql> SELECT MATCH(c) AGAINST('I\'d') FROM t;
+-----+
| MATCH(c) AGAINST('I\'d') |
+-----+
| 0 |

```

Note how neither “case” nor “insensitive” match “case-insensitive” the way that they would for the built-in parser.

MySQL plugins can be written in C or C++ (or another language that can use C calling conventions). One feature of C++ is that you can use non-constant variables to initialize global structures. However, if you write a C++ plugin, you should not use this feature. Members of structures such as the `st_mysql_plugin` structure should be initialized with constant variables. The `simple_parser` descriptor shown earlier is allowable in a C++ plugin because it satisfies that requirement:

```
mysql_declare_plugin
{
 MYSQL_FTPARSER_PLUGIN, /* type */
 &simple_parser_descriptor, /* descriptor */
 "simple_parser", /* name */
}
```

```
"MySQL AB", /* author */
"Simple Full-Text Parser", /* description */
PLUGIN_LICENSE_GPL, /* plugin license */
simple_parser_plugin_init, /* init function (when loaded) */
simple_parser_plugin_deinit, /* deinit function (when unloaded) */
0x0001, /* version */
simple_status /* status variables */
}
mysql_declare_plugin_end;
```

Here is another valid way to write the descriptor. It uses constant variables to indicate the plugin name, author, and description:

```
const char *simple_parser_name = "simple_parser";
const char *simple_parser_author = "MySQL AB";
const char *simple_parser_description = "Simple Full-Text Parser";

mysql_declare_plugin
{
 MYSQL_FTPARSER_PLUGIN, /* type */
 &simple_parser_descriptor, /* descriptor */
 simple_parser_name, /* name */
 simple_parser_author, /* author */
 simple_parser_description, /* description */
 PLUGIN_LICENSE_GPL, /* plugin license */
 simple_parser_plugin_init, /* init function (when loaded) */
 simple_parser_plugin_deinit, /* deinit function (when unloaded) */
 0x0001, /* version */
 simple_status /* status variables */
}
mysql_declare_plugin_end;
```

However, the following descriptor is invalid. It uses structure members to indicate the plugin name, author, and description, but structures are not considered constant initializers in C++:

```
typedef struct
{
 const char *name;
 const char *author;
 const char *description;
} plugin_info;

plugin_info parser_info = {
 "simple_parser",
 "MySQL AB",
 "Simple Full-Text Parser"
};

mysql_declare_plugin
{
 MYSQL_FTPARSER_PLUGIN, /* type */
 &simple_parser_descriptor, /* descriptor */
 parser_info.name, /* name */
 parser_info.author, /* author */
 parser_info.description, /* description */
 PLUGIN_LICENSE_GPL, /* plugin license */
 simple_parser_plugin_init, /* init function (when loaded) */
 simple_parser_plugin_deinit, /* deinit function (when unloaded) */
 0x0001, /* version */
 simple_status /* status variables */
}
mysql_declare_plugin_end;
```

### 31.3. Adding New Functions to MySQL

There are three ways to add new functions to MySQL:

- You can add functions through the user-defined function (UDF) interface. User-defined functions are compiled as object files and then added to and removed from the server dynamically using the `CREATE FUNCTION` and `DROP FUNCTION` statements. See [Section 31.3.2, “CREATE FUNCTION Syntax”](#).
- You can add functions as native (built-in) MySQL functions. Native functions are compiled into the `mysqld` server and become available on a permanent basis.
- Another way to add functions is by creating stored functions. These are written using SQL statements rather than by compiling object code. The syntax for writing stored functions is not covered here. See [Chapter 22, Stored Procedures and Functions](#).

Each method of creating compiled functions has advantages and disadvantages:

- If you write user-defined functions, you must install object files in addition to the server itself. If you compile your function in-

to the server, you don't need to do that.

- Native functions require you to modify a source distribution. UDFs do not. You can add UDFs to a binary MySQL distribution. No access to MySQL source is necessary.
- If you upgrade your MySQL distribution, you can continue to use your previously installed UDFs, unless you upgrade to a newer version for which the UDF interface changes. For native functions, you must repeat your modifications each time you upgrade.

Whichever method you use to add new functions, they can be invoked in SQL statements just like native functions such as `ABS()` or `SOUNDEX()`.

See [Section 8.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

The following sections describe features of the UDF interface, provide instructions for writing UDFs, discuss security precautions that MySQL takes to prevent UDF misuse, and describe how to add native MySQL functions.

For example source code that illustrates how to write UDFs, take a look at the `sql/udf_example.c` file that is provided in MySQL source distributions.

### 31.3.1. Features of the User-Defined Function Interface

The MySQL interface for user-defined functions provides the following features and capabilities:

- Functions can return string, integer, or real values and can accept arguments of those same types.
- You can define simple functions that operate on a single row at a time, or aggregate functions that operate on groups of rows.
- Information is provided to functions that enables them to check the number, types, and names of the arguments passed to them.
- You can tell MySQL to coerce arguments to a given type before passing them to a function.
- You can indicate that a function returns `NULL` or that an error occurred.

### 31.3.2. CREATE FUNCTION Syntax

```
CREATE [AGGREGATE] FUNCTION function_name RETURNS {STRING|INTEGER|REAL|DECIMAL}
SONAME shared_library_name
```

A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`.

*function\_name* is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

*shared\_library\_name* is the basename of the shared object file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable.

#### Note

This is a change in MySQL 5.1. For earlier versions of MySQL, the shared object can be located in any directory that is searched by your system's dynamic linker.

To create a function, you must have the `INSERT` privilege for the `mysql` database. This is necessary because `CREATE FUNCTION` adds a row to the `mysql.func` system table that records the function's name, type, and shared library name. If you do not have this table, you should run the `mysql_upgrade` command to create it. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see [Section 31.3.4, “Adding a New User-Defined Function”](#). For the UDF mechanism to work, functions must be written in C or C++ (or another language that can use C calling conventions), your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

An `AGGREGATE` function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`. For `AGGREGATE` to work, your `mysql.func` table must contain a `type` column. If your `mysql.func` table does not have this column, you should run the `mysql_upgrade` program to create it (see Section 4.4.8, “`mysql_upgrade` — Check Tables for MySQL Upgrade”).

**Note**

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

### 31.3.3. DROP FUNCTION Syntax

```
DROP FUNCTION function_name
```

This statement drops the user-defined function (UDF) named `function_name`.

To drop a function, you must have the `DELETE` privilege for the `mysql` database. This is because `DROP FUNCTION` removes a row from the `mysql.func` system table that records the function's name, type, and shared library name.

**Note**

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

`DROP FUNCTION` is also used to drop stored functions (see Section 22.2.3, “`DROP PROCEDURE and DROP FUNCTION Syntax`”).

### 31.3.4. Adding a New User-Defined Function

For the UDF mechanism to work, functions must be written in C or C++ and your operating system must support dynamic loading. The MySQL source distribution includes a file `sql/udf_example.c` that defines 5 new functions. Consult this file to see how UDF calling conventions work. UDF-related symbols and data structures are defined in the `include/mysql_com.h` header file. (You need not include this header file directly because it is included by `mysql.h`.)

A UDF contains code that becomes part of the running server, so when you write a UDF, you are bound by any and all constraints that otherwise apply to writing server code. For example, you may have problems if you attempt to use functions from the `libstdc++` library. These constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to UDFs that were originally written for older servers. For information about these constraints, see Section 2.9.2, “`Typical configure Options`”, and Section 2.9.4, “`Dealing with Problems Compiling MySQL`”.

To be able to use UDFs, you need to link `mysqld` dynamically. Don't configure MySQL using `-with-mysqld-ldflags=-all-static`. If you want to use a UDF that needs to access symbols from `mysqld` (for example, the `metaphone` function in `sql/udf_example.c` that uses `default_charset_info`), you must link the program with `-rdynamic` (see `man dlopen`). If you plan to use UDFs, the rule of thumb is to configure MySQL with `-with-mysqld-ldflags=-rdynamic` unless you have a very good reason not to.

For each function that you want to use in SQL statements, you should define corresponding C (or C++) functions. In the following discussion, the name “xxx” is used for an example function name. To distinguish between SQL and C/C++ usage, `XXX()` (uppercase) indicates an SQL function call, and `xxx()` (lowercase) indicates a C/C++ function call.

The C/C++ functions that you write to implement the interface for `XXX()` are:

- `xxx()` (required)

The main function. This is where the function result is computed. The correspondence between the SQL function data type and the return type of your C/C++ function is shown here:

SQL Type	C/C++ Type
STRING	char *
INTEGER	long long
REAL	double

It is also possible to declare a `DECIMAL` function, but currently the value is returned as a string, so you should write the UDF as

though it were a `STRING` function. `ROW` functions are not implemented.

- `xxx_init()` (optional)

The initialization function for `xxx()`. It can be used for the following purposes:

- To check the number of arguments to `xxx()`.
- To check that the arguments are of a required type or, alternatively, to tell MySQL to coerce arguments to the types you want when the main function is called.
- To allocate any memory required by the main function.
- To specify the maximum length of the result.
- To specify (for `REAL` functions) the maximum number of decimal places in the result.
- To specify whether the result can be `NULL`.

- `xxx_deinit()` (optional)

The deinitialization function for `xxx()`. It should deallocate any memory allocated by the initialization function.

When an SQL statement invokes `xxx()`, MySQL calls the initialization function `xxx_init()` to let it perform any required setup, such as argument checking or memory allocation. If `xxx_init()` returns an error, MySQL aborts the SQL statement with an error message and does not call the main or deinitialization functions. Otherwise, MySQL calls the main function `xxx()` once for each row. After all rows have been processed, MySQL calls the deinitialization function `xxx_deinit()` so that it can perform any required cleanup.

For aggregate functions that work like `SUM()`, you must also provide the following functions:

- `xxx_clear()` (required in 5.1)

Reset the current aggregate value but do not insert the argument as the initial aggregate value for a new group.

- `xxx_add()` (required)

Add the argument to the current aggregate value.

MySQL handles aggregate UDFs as follows:

1. Call `xxx_init()` to let the aggregate function allocate any memory it needs for storing results.
2. Sort the table according to the `GROUP BY` expression.
3. Call `xxx_clear()` for the first row in each new group.
4. Call `xxx_add()` for each new row that belongs in the same group.
5. Call `xxx()` to get the result for the aggregate when the group changes or after the last row has been processed.
6. Repeat 3-5 until all rows has been processed
7. Call `xxx_deinit()` to let the UDF free any memory it has allocated.

All functions must be thread-safe. This includes not just the main function, but the initialization and deinitialization functions as well, and also the additional functions required by aggregate functions. A consequence of this requirement is that you are not allowed to allocate any global or static variables that change! If you need memory, you should allocate it in `xxx_init()` and free it in `xxx_deinit()`.

### 31.3.4.1. UDF Calling Sequences for Simple Functions

This section describes the different functions that you need to define when you create a simple UDF. [Section 31.3.4, “Adding a New User-Defined Function”](#), describes the order in which MySQL calls these functions.

The main `xxx()` function should be declared as shown in this section. Note that the return type and parameters differ, depending on whether you declare the SQL function `xxx()` to return `STRING`, `INTEGER`, or `REAL` in the `CREATE FUNCTION` statement:

For **STRING** functions:

```
char *xxx(UDF_INIT *initid, UDF_ARGS *args,
 char *result, unsigned long *length,
 char *is_null, char *error);
```

For **INTEGER** functions:

```
long long xxx(UDF_INIT *initid, UDF_ARGS *args,
 char *is_null, char *error);
```

For **REAL** functions:

```
double xxx(UDF_INIT *initid, UDF_ARGS *args,
 char *is_null, char *error);
```

**DECIMAL** functions return string values and should be declared the same way as **STRING** functions. **ROW** functions are not implemented.

The initialization and deinitialization functions are declared like this:

```
my_bool xxx_init(UDF_INIT *initid, UDF_ARGS *args, char *message);
void xxx_deinit(UDF_INIT *initid);
```

The `initid` parameter is passed to all three functions. It points to a `UDF_INIT` structure that is used to communicate information between functions. The `UDF_INIT` structure members follow. The initialization function should fill in any members that it wishes to change. (To use the default for a member, leave it unchanged.)

- `my_bool maybe_null`

`xxx_init()` should set `maybe_null` to 1 if `xxx()` can return `NULL`. The default value is 1 if any of the arguments are declared `maybe_null`.

- `unsigned int decimals`

The number of decimal digits to the right of the decimal point. The default value is the maximum number of decimal digits in the arguments passed to the main function. (For example, if the function is passed `1.34`, `1.345`, and `1.3`, the default would be 3, because `1.345` has 3 decimal digits.)

- `unsigned int max_length`

The maximum length of the result. The default `max_length` value differs depending on the result type of the function. For string functions, the default is the length of the longest argument. For integer functions, the default is 21 digits. For real functions, the default is 13 plus the number of decimal digits indicated by `initid->decimals`. (For numeric functions, the length includes any sign or decimal point characters.)

If you want to return a blob value, you can set `max_length` to 65KB or 16MB. This memory is not allocated, but the value is used to decide which data type to use if there is a need to temporarily store the data.

- `char *ptr`

A pointer that the function can use for its own purposes. For example, functions can use `initid->ptr` to communicate allocated memory among themselves. `xxx_init()` should allocate the memory and assign it to this pointer:

```
initid->ptr = allocated_memory;
```

In `xxx()` and `xxx_deinit()`, refer to `initid->ptr` to use or deallocate the memory.

- `my_bool const_item`

`xxx_init()` should set `const_item` to 1 if `xxx()` always returns the same value and to 0 otherwise.

### 31.3.4.2. UDF Calling Sequences for Aggregate Functions

This section describes the different functions that you need to define when you create an aggregate UDF. [Section 31.3.4, “Adding a New User-Defined Function”](#), describes the order in which MySQL calls these functions.

- `xxx_reset()`

This function is called when MySQL finds the first row in a new group. It should reset any internal summary variables and then use the given `UDF_ARGS` argument as the first value in your internal summary value for the group. Declare `xxx_reset()` as follows:

```
char *xxx_reset(UDF_INIT *initid, UDF_ARGS *args,
 char *is_null, char *error);
```

`xxx_reset()` is not needed or used in MySQL 5.1, in which the UDF interface uses `xxx_clear()` instead. However, you can define both `xxx_reset()` and `xxx_clear()` if you want to have your UDF work with older versions of the server. (If you do include both functions, the `xxx_reset()` function in many cases can be implemented internally by calling `xxx_clear()` to reset all variables, and then calling `xxx_add()` to add the `UDF_ARGS` argument as the first value in the group.)

- `xxx_clear()`

This function is called when MySQL needs to reset the summary results. It is called at the beginning for each new group but can also be called to reset the values for a query where there were no matching rows. Declare `xxx_clear()` as follows:

```
char *xxx_clear(UDF_INIT *initid, char *is_null, char *error);
```

`is_null` is set to point to `CHAR(0)` before calling `xxx_clear()`.

If something went wrong, you can store a value in the variable to which the `error` argument points. `error` points to a single-byte variable, not to a string buffer.

`xxx_clear()` is required by MySQL 5.1.

- `xxx_add()`

This function is called for all rows that belong to the same group, except for the first row. You should use it to add the value in the `UDF_ARGS` argument to your internal summary variable.

```
char *xxx_add(UDF_INIT *initid, UDF_ARGS *args,
 char *is_null, char *error);
```

The `xxx()` function for an aggregate UDF should be declared the same way as for a non-aggregate UDF. See [Section 31.3.4.1, “UDF Calling Sequences for Simple Functions”](#).

For an aggregate UDF, MySQL calls the `xxx()` function after all rows in the group have been processed. You should normally never access its `UDF_ARGS` argument here but instead return a value based on your internal summary variables.

Return value handling in `xxx()` should be done the same way as for a non-aggregate UDF. See [Section 31.3.4.4, “UDF Return Values and Error Handling”](#).

The `xxx_reset()` and `xxx_add()` functions handle their `UDF_ARGS` argument the same way as functions for non-aggregate UDFs. See [Section 31.3.4.3, “UDF Argument Processing”](#).

The pointer arguments to `is_null` and `error` are the same for all calls to `xxx_reset()`, `xxx_clear()`, `xxx_add()` and `xxx()`. You can use this to remember that you got an error or whether the `xxx()` function should return `NULL`. You should not store a string into `*error`! `error` points to a single-byte variable, not to a string buffer.

`*is_null` is reset for each group (before calling `xxx_clear()`). `*error` is never reset.

If `*is_null` or `*error` are set when `xxx()` returns, MySQL returns `NULL` as the result for the group function.

### 31.3.4.3. UDF Argument Processing

The `args` parameter points to a `UDF_ARGS` structure that has the members listed here:

- `unsigned int arg_count`

The number of arguments. Check this value in the initialization function if you require your function to be called with a particular number of arguments. For example:

```
if (args->arg_count != 2)
{
 strcpy(message, "XXX() requires two arguments");
```

```

return 1;
}

```

For other `UDF_ARGS` member values that are arrays, array references are zero-based. That is, refer to array members using index values from 0 to `args->arg_count - 1`.

- `enum Item_result *arg_type`

A pointer to an array containing the types for each argument. The possible type values are `STRING_RESULT`, `INT_RESULT`, `REAL_RESULT`, and `DECIMAL_RESULT`.

To make sure that arguments are of a given type and return an error if they are not, check the `arg_type` array in the initialization function. For example:

```

if (args->arg_type[0] != STRING_RESULT ||
 args->arg_type[1] != INT_RESULT)
{
 strcpy(message, "XXX() requires a string and an integer");
 return 1;
}

```

Arguments of type `DECIMAL_RESULT` are passed as strings, so you should handle them the same way as `STRING_RESULT` values.

As an alternative to requiring your function's arguments to be of particular types, you can use the initialization function to set the `arg_type` elements to the types you want. This causes MySQL to coerce arguments to those types for each call to `xxx()`. For example, to specify that the first two arguments should be coerced to string and integer, respectively, do this in `xxx_init()`:

```

args->arg_type[0] = STRING_RESULT;
args->arg_type[1] = INT_RESULT;

```

Exact-value decimal arguments such as `1.3` or `DECIMAL` column values are passed with a type of `DECIMAL_RESULT`. However, the values are passed as strings. If you want to receive a number, use the initialization function to specify that the argument should be coerced to a `REAL_RESULT` value:

```

args->arg_type[2] = REAL_RESULT;

```

- `char **args`

`args->args` communicates information to the initialization function about the general nature of the arguments passed to your function. For a constant argument `i`, `args->args[i]` points to the argument value. (See below for instructions on how to access the value properly.) For a non-constant argument, `args->args[i]` is 0. A constant argument is an expression that uses only constants, such as `3` or `4*7-2` or `SIN(3.14)`. A non-constant argument is an expression that refers to values that may change from row to row, such as column names or functions that are called with non-constant arguments.

For each invocation of the main function, `args->args` contains the actual arguments that are passed for the row currently being processed.

If argument `i` represents `NULL`, `args->args[i]` is a null pointer (0). If the argument is not `NULL`, functions can refer to it as follows:

- An argument of type `STRING_RESULT` is given as a string pointer plus a length, to allow handling of binary data or data of arbitrary length. The string contents are available as `args->args[i]` and the string length is `args->lengths[i]`. Do not assume that the string is null-terminated.
- For an argument of type `INT_RESULT`, you must cast `args->args[i]` to a `long long` value:

```

long long int_val;
int_val = *((long long*) args->args[i]);

```

- For an argument of type `REAL_RESULT`, you must cast `args->args[i]` to a `double` value:

```

double real_val;
real_val = *((double*) args->args[i]);

```

- For an argument of type `DECIMAL_RESULT`, the value is passed as a string and should be handled like a `STRING_RESULT` value.
- `ROW_RESULT` arguments are not implemented.

- `unsigned long *lengths`

For the initialization function, the `lengths` array indicates the maximum string length for each argument. You should not change these. For each invocation of the main function, `lengths` contains the actual lengths of any string arguments that are passed for the row currently being processed. For arguments of types `INT_RESULT` or `REAL_RESULT`, `lengths` still contains the maximum length of the argument (as for the initialization function).

- `char *maybe_null`

For the initialization function, the `maybe_null` array indicates for each argument whether the argument value might be null (0 if no, 1 if yes).

- `char **attributes`

`args->attributes` communicates information about the names of the UDF arguments. For argument `i`, the attribute name is available as a string in `args->attributes[i]` and the attribute length is `args->attribute_lengths[i]`. Do not assume that the string is null-terminated.

By default, the name of a UDF argument is the text of the expression used to specify the argument. For UDFs, an argument may also have an optional `[AS] alias_name` clause, in which case the argument name is `alias_name`. The `attributes` value for each argument thus depends on whether an alias was given.

Suppose that a UDF `my_udf()` is invoked as follows:

```
SELECT my_udf(expr1, expr2 AS alias1, expr3 alias2);
```

In this case, the `attributes` and `attribute_lengths` arrays will have these values:

```
args->attributes[0] = "expr1"
args->attribute_lengths[0] = 5

args->attributes[1] = "alias1"
args->attribute_lengths[1] = 6

args->attributes[2] = "alias2"
args->attribute_lengths[2] = 6
```

- `unsigned long *attribute_lengths`

The `attribute_lengths` array indicates the length of each argument name.

### 31.3.4.4. UDF Return Values and Error Handling

The initialization function should return `0` if no error occurred and `1` otherwise. If an error occurs, `xxx_init()` should store a null-terminated error message in the `message` parameter. The message is returned to the client. The message buffer is `MYSQL_ERRMSG_SIZE` characters long, but you should try to keep the message to less than 80 characters so that it fits the width of a standard terminal screen.

The return value of the main function `xxx()` is the function value, for `long long` and `double` functions. A string function should return a pointer to the result and set `*result` and `*length` to the contents and length of the return value. For example:

```
memcpy(result, "result string", 13);
*length = 13;
```

The `result` buffer that is passed to the `xxx()` function is 255 bytes long. If your result fits in this, you don't have to worry about memory allocation for results.

If your string function needs to return a string longer than 255 bytes, you must allocate the space for it with `malloc()` in your `xxx_init()` function or your `xxx()` function and free it in your `xxx_deinit()` function. You can store the allocated memory in the `ptr` slot in the `UDF_INIT` structure for reuse by future `xxx()` calls. See Section 31.3.4.1, “UDF Calling Sequences for Simple Functions”.

To indicate a return value of `NULL` in the main function, set `*is_null` to 1:

```
*is_null = 1;
```

To indicate an error return in the main function, set `*error` to 1:

```
*error = 1;
```

If `xxx()` sets `*error` to 1 for any row, the function value is `NULL` for the current row and for any subsequent rows processed by the statement in which `XXX()` was invoked. (`xxx()` is not even called for subsequent rows.)

### 31.3.4.5. Compiling and Installing User-Defined Functions

Files implementing UDFs must be compiled and installed on the host where the server runs. This process is described below for the example UDF file `sql/udf_example.c` that is included in the MySQL source distribution.

The immediately following instructions are for Unix. Instructions for Windows are given later in this section.

The `udf_example.c` file contains the following functions:

- `metaphon()` returns a metaphon string of the string argument. This is something like a soundex string, but it's more tuned for English.
- `myfunc_double()` returns the sum of the ASCII values of the characters in its arguments, divided by the sum of the length of its arguments.
- `myfunc_int()` returns the sum of the length of its arguments.
- `sequence([const int])` returns a sequence starting from the given number or 1 if no number has been given.
- `lookup()` returns the IP number for a hostname.
- `reverse_lookup()` returns the hostname for an IP number. The function may be called either with a single string argument of the form `'xxx.xxx.xxx.xxx'` or with four numbers.

A dynamically loadable file should be compiled as a sharable object file, using a command something like this:

```
shell> gcc -shared -o udf_example.so udf_example.c
```

If you are using `gcc` with `configure` and `libtool` (which is how MySQL is configured), you should be able to create `udf_example.so` with a simpler command:

```
shell> make udf_example.la
```

After you compile a shared object containing UDFs, you must install it and tell MySQL about it. Compiling a shared object from `udf_example.c` using `gcc` directly produces a file named `udf_example.so`. Compiling the shared object using `make` produces a file named something like `udf_example.so.0.0.0` in the `.libs` directory (the exact name may vary from platform to platform). Copy the shared object to the server's plugin directory and name it `udf_example.so`. This directory is given by the value of the `plugin_dir` system variable.

#### Note

This is a change in MySQL 5.1. For earlier versions of MySQL, the shared object can be located in any directory that is searched by your system's dynamic linker.

On some systems, the `ldconfig` program that configures the dynamic linker does not recognize a shared object unless its name begins with `lib`. In this case you should rename a file such as `udf_example.so` to `libudf_example.so`.

On Windows, you can compile user-defined functions by using the following procedure:

1. You need to obtain the Bazaar source repository for MySQL 5.1. See [Section 2.9.3, "Installing from the Development Source Tree"](#).
2. You must obtain the CMake build utility from <http://www.cmake.org>. (Version 2.4.2 or later is required).
3. In the source repository, look in the `sql` directory. There are files named `udf_example.def` and `udf_example.c` there. Copy both files from this directory to your working directory.
4. Create a CMake `makefile` with these contents:

```
PROJECT(udf_example)

Path for MySQL include directory
INCLUDE_DIRECTORIES("c:/mysql/include")

ADD_DEFINITIONS("-DHAVE_DLOPEN")
ADD_LIBRARY(udf_example MODULE udf_example.c udf_example.def)
```

```
TARGET_LINK_LIBRARIES(udf_example wsock32)
```

5. Create the VC project and solution files:

```
cmake -G "<Generator>"
```

Invoking `cmake --help` shows you a list of valid Generators.

6. Create `udf_example.dll`:

```
devenv udf_example.sln /build Release
```

After the shared object file has been installed, notify `mysqld` about the new functions with these statements:

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_double RETURNS REAL SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_int RETURNS INTEGER SONAME 'udf_example.so';
mysql> CREATE FUNCTION lookup RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION reverse_lookup
-> RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE AGGREGATE FUNCTION avgcost
-> RETURNS REAL SONAME 'udf_example.so';
```

Functions can be deleted using `DROP FUNCTION`:

```
mysql> DROP FUNCTION metaphon;
mysql> DROP FUNCTION myfunc_double;
mysql> DROP FUNCTION myfunc_int;
mysql> DROP FUNCTION lookup;
mysql> DROP FUNCTION reverse_lookup;
mysql> DROP FUNCTION avgcost;
```

The `CREATE FUNCTION` and `DROP FUNCTION` statements update the `func` system table in the `mysql` database. The function's name, type and shared library name are saved in the table. You must have the `INSERT` and `DELETE` privileges for the `mysql` database to create and drop functions.

You should not use `CREATE FUNCTION` to add a function that has previously been created. If you need to reinstall a function, you should remove it with `DROP FUNCTION` and then reinstall it with `CREATE FUNCTION`. You would need to do this, for example, if you recompile a new version of your function, so that `mysqld` gets the new version. Otherwise, the server continues to use the old version.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

If the new function will be referred to in statements that will be replicated to slave servers, you must ensure that every slave server also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

### 31.3.4.6. User-Defined Function Security Precautions

MySQL takes the following measures to prevent misuse of user-defined functions.

You must have the `INSERT` privilege to be able to use `CREATE FUNCTION` and the `DELETE` privilege to be able to use `DROP FUNCTION`. This is necessary because these statements add and delete rows from the `mysql.func` table.

UDFs should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. `mysqld` also supports an `--allow-suspicious-udfs` option that controls whether UDFs that have only an `xxx` symbol can be loaded. By default, the option is off, to prevent attempts at loading functions from shared object files other than those containing legitimate UDFs. If you have older UDFs that contain only the `xxx` symbol and that cannot be recompiled to include an auxiliary symbol, it may be necessary to specify the `--allow-suspicious-udfs` option. Otherwise, you should avoid enabling this capability.

UDF object files cannot be placed in arbitrary directories. They must be located in the server's plugin directory. This directory is given by the value of the `plugin_dir` system variable.

#### Note

This is a change in MySQL 5.1. For earlier versions of MySQL, the shared object can be located in any directory that is searched by your system's dynamic linker.

### 31.3.5. Adding a New Native Function

To add a new native MySQL function, use the procedure described here, which requires that you use a source distribution. You cannot add native functions to a binary distribution because it is necessary to modify MySQL source code and compile MySQL from the modified source. If you migrate to another version of MySQL (for example, when a new version is released), you must repeat the procedure with the new version.

If the new native function will be referred to in statements that will be replicated to slave servers, you must ensure that every slave server also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

To add a new native function, follow these steps to modify source files in the `sql` directory. For MySQL 5.1, the first two steps apply only as of 5.1.13. For older versions, see the instructions in the corresponding section of the MySQL 5.0 manual.

1. Create a subclass for the function in `item_create.cc`:
  - If the function takes a fixed number of arguments, create a subclass of `Create_func_arg0`, `Create_func_arg1`, `Create_func_arg2`, or `Create_func_arg3`, respectively, depending on whether the function takes zero, one, two, or three arguments. For examples, see the `Create_func_uuid`, `Create_func_abs`, `Create_func_pow`, and `Create_func_lpad` classes.
  - If the function takes a variable number of arguments, create a subclass of `Create_native_func`. For an example, see `Create_func_concat`.
2. To provide a name by which the function can be referred to in SQL statements, register the name in `item_create.cc` by adding a line to this array:

```
static Native_func_registry func_array[]
```

You can register several names for the same function. For example, see the lines for "LCASE" and "LOWER", which are aliases for `Create_func_lcase`.

3. In `item_func.h`, declare a class inheriting from `Item_num_func` or `Item_str_func`, depending on whether your function returns a number or a string.
4. In `item_func.cc`, add one of the following declarations, depending on whether you are defining a numeric or string function:

```
double Item_func_newname::val()
longlong Item_func_newname::val_int()
String *Item_func_newname::Str(String *str)
```

If you inherit your object from any of the standard items (like `Item_num_func`), you probably only have to define one of these functions and let the parent object take care of the other functions. For example, the `Item_str_func` class defines a `val()` function that executes `atof()` on the value returned by `::str()`.

5. If the function is non-deterministic, include the following statement in the item constructor to indicate that function results should not be cached:

```
current_thd->lex->safe_to_cache_query=0;
```

A function is non-deterministic if, given fixed values for its arguments, it can return different results for different invocations.

6. You should probably also define the following object function:

```
void Item_func_newname::fix_length_and_dec()
```

This function should at least calculate `max_length` based on the given arguments. `max_length` is the maximum number of characters the function may return. This function should also set `maybe_null = 0` if the main function can't return a `NULL` value. The function can check whether any of the function arguments can return `NULL` by checking the arguments' `maybe_null` variable. Look at `Item_func_mod::fix_length_and_dec` for a typical example of how to do this.

All functions must be thread-safe. In other words, do not use any global or static variables in the functions without protecting them with mutexes.

If you want to return `NULL` from `::val()`, `::val_int()`, or `::str()`, you should set `null_value` to 1 and return 0.

For `::str()` object functions, there are additional considerations to be aware of:

- The `String *str` argument provides a string buffer that may be used to hold the result. (For more information about the `String` type, take a look at the `sql_string.h` file.)
- The `::str()` function should return the string that holds the result, or `(char*) 0` if the result is `NULL`.
- All current string functions try to avoid allocating any memory unless absolutely necessary!

## 31.4. Adding New Procedures to MySQL

In MySQL, you can define a procedure in C++ that can access and modify the data in a query before it is sent to the client. The modification can be done on a row-by-row or `GROUP BY` level.

We have created an example procedure to show you what can be done.

Additionally, we recommend that you take a look at `mysqlua`. With this you can use the LUA language to load a procedure at runtime into `mysqld`.

### 31.4.1. PROCEDURE ANALYSE

```
analyse([max_elements[,max_memory]])
```

This procedure is defined in the `sql/sql_analyse.cc` file. It examines the result from a query and returns an analysis of the results that suggests optimal data types for each column. To obtain this analysis, append `PROCEDURE ANALYSE` to the end of a `SELECT` statement:

```
SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements,[max_memory]])
```

For example:

```
SELECT col1, col2 FROM table1 PROCEDURE ANALYSE(10, 2000);
```

The results show some statistics for the values returned by the query, and propose an optimal data type for the columns. This can be helpful for checking your existing tables, or after importing new data. You may need to try different settings for the arguments so that `PROCEDURE ANALYSE()` does not suggest the `ENUM` data type when it is not appropriate.

The arguments are optional and are used as follows:

- `max_elements` (default 256) is the maximum number of distinct values that `analyse` notices per column. This is used by `analyse` to check whether the optimal data type should be of type `ENUM`.
- `max_memory` (default 8192) is the maximum amount of memory that `analyse` should allocate per column while trying to find all distinct values.

### 31.4.2. Writing a Procedure

For the moment, the only documentation for this is the source.

You can find all information about procedures by examining the following files:

- `sql/sql_analyse.cc`
- `sql/procedure.h`
- `sql/procedure.cc`
- `sql/sql_select.cc`

## 31.5. Debugging and Porting MySQL

This appendix helps you port MySQL to other operating systems. Do check the list of currently supported operating systems first. See [Section 2.1.1, “Operating Systems Supported by MySQL Community Server”](#). If you have created a new port of MySQL, please let us know so that we can list it here and on our Web site (<http://www.mysql.com/>), recommending it to other users.

Note: If you create a new port of MySQL, you are free to copy and distribute it under the GPL license, but it does not make you a copyright holder of MySQL.

A working POSIX thread library is needed for the server. On Solaris 2.5 we use Sun PThreads (the native thread support in 2.4 and earlier versions is not good enough), on Linux we use LinuxThreads by Xavier Leroy, <Xavier.Leroy@inria.fr>.

The hard part of porting to a new Unix variant without good native thread support is probably to port MIT-pthreads. See [mit-pthreads/README](http://mit-pthreads.org/README) and Programming POSIX Threads (<http://www.humanfactor.com/pthreads/>).

Up to MySQL 4.0.2, the MySQL distribution included a patched version of Chris Provenzano's Pthreads from MIT (see the MIT Pthreads Web page at <http://www.mit.edu/afs/sipb/project/pthreads/> and a programming introduction at [http://www.mit.edu:8001/people/proven/IAP\\_2000/](http://www.mit.edu:8001/people/proven/IAP_2000/)). These can be used for some operating systems that do not have POSIX threads. See Section 2.9.5, “MIT-pthreads Notes”.

It is also possible to use another user level thread package named FSU Pthreads (see <http://moss.csc.ncsu.edu/~mueller/pthreads/>). This implementation is being used for the SCO port.

See the `thr_lock.c` and `thr_alarm.c` programs in the `mysys` directory for some tests/examples of these problems.

Both the server and the client need a working C++ compiler. We use `gcc` on many platforms. Other compilers that are known to work are SPARCworks, Sun Forte, Irix `cc`, HP-UX `aCC`, IBM AIX `x1C_r`, Intel `ecc/icc` and Compaq `cxx`.

### Important

If you are trying to build MySQL 5.1 with `icc` on the IA64 platform, and need support for MySQL Cluster, you should first ensure that you are using `icc` version 9.1.043 or later. (For details, see [Bug#21875](#).)

To compile only the client use `./configure --without-server`.

There is currently no support for only compiling the server, nor is it likely to be added unless someone has a good reason for it.

If you want/need to change any `Makefile` or the configure script you also need GNU Automake and Autoconf. See Section 2.9.3, “Installing from the Development Source Tree”.

All steps needed to remake everything from the most basic files.

```
/bin/rm */.deps/*.P
/bin/rm -f config.cache
aclocal
autoheader
aclocal
automake
autoconf
./configure --with-debug=full --prefix='your installation directory'

The makefiles generated above need GNU make 3.75 or newer.
(called gmake below)
gmake clean all install init-db
```

If you run into problems with a new port, you may have to do some debugging of MySQL! See Section 31.5.1, “Debugging a MySQL Server”.

### Note

Before you start debugging `mysqld`, first get the test programs `mysys/thr_alarm` and `mysys/thr_lock` to work. This ensures that your thread installation has even a remote chance to work!

## 31.5.1. Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` (which disables all new, potentially unsafe functionality) or with `--safe-mode` which disables a lot of optimization that may cause problems. See Section B.1.4.2, “What to Do If MySQL Keeps Crashing”.

If `mysqld` doesn't want to start, you should verify that you don't have any `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld -no-defaults ...`.

If `mysqld` starts to eat up CPU or memory or if it “hangs,” you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients can't connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you haven't compiled

MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See [Chapter 5, MySQL Server Administration](#). You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See [Section 2.13, “Operating System-Specific Notes”](#).

### 31.5.1.1. Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `--with-debug` or the `--with-debug=full` option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysqld . . . --debug` in this case.

If you are using `gcc`, the recommended `configure` line is:

```
CC=gcc CFLAGS="-O2" CXX=gcc CXXFLAGS="-O2 -felide-constructors \
-fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql \
--with-debug --with-extra-charsets=complex
```

This avoids problems with the `libstdc++` library and with C++ exceptions (many compilers have problems with C++ exceptions in threaded code) and compile a MySQL version with support for all character sets.

If you suspect a memory overrun error, you can configure MySQL with `--with-debug=full`, which installs a memory allocation (`SAFEMALLOC`) checker. However, running with `SAFEMALLOC` is quite slow, so if you get performance problems you should start `mysqld` with the `--skip-safemalloc` option. This disables the memory overrun checks for each call to `malloc()` and `free()`.

If `mysqld` stops crashing when you compile it with `--with-debug`, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` to the `CFLAGS` and `CXXFLAGS` variables above and not use `--with-debug`. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something “unexpected,” an entry is written to `stderr`, which `mysqld_safe` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging! (The second thing is to send mail to a MySQL mailing list and ask for help. See [Section 1.6.1, “MySQL Mailing Lists”](#). If you believe that you have found a bug, please use the instructions at [Section 1.7, “How to Report Bugs or Problems”](#)).

In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files.

### 31.5.1.2. Creating Trace Files

If the `mysqld` server doesn't start or if you can cause it to crash quickly, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld -V`. If the version number ends with `-debug`, it's compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld` as of MySQL 4.1.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `C:\mysqld.trace` on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start `mysqld` as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`.

Note that the trace file become **very big**! If you want to generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:0,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you make a bug report about this, please only send the lines from the trace file to the appropriate mailing list where something

seems to go wrong! If you can't locate the wrong place, you can ftp the trace file, together with a full bug report, to <ftp://ftp.mysql.com/pub/mysql/upload/> so that a MySQL developer can take a look at it.

The trace file is made with the **DBUG** package by Fred Fish. See [Section 31.5.3, “The DBUG Package”](#).

### 31.5.1.3. Using `pdb` to create a Windows crashdump

Starting with MySQL 5.1.12 the Program Database files (extension `pdb`) are included in the Noinstall distribution of MySQL. These files provide information for debugging your MySQL installation in the event of a problem.

The PDB file contains more detailed information about `mysqld` and other tools that enables more detailed trace and dump files to be created. You can use these with Dr Watson, `WinDbg` and Visual Studio to debug `mysqld`.

For more information on PDB files, see [Microsoft Knowledge Base Article 121366](#). For more information on the debugging options available, see [Debugging Tools for Windows](#).

Dr Watson is installed with all Windows distributions, but if you have installed Windows development tools, Dr Watson may have been replaced with `WinDbg`, the debugger included with Visual Studio, or the debugging tools provided with Borland or Delphi.

To generate a crash file using Dr Watson, follow these steps:

1. Start Dr Watson by running `drwtsn32.exe` interactively using the `-i` option:

```
C:\> drwtsn32 -i
```

2. Set the **LOG FILE PATH** to the directory where you want to store trace files.
3. Make sure **DUMP ALL THREAD CONTEXTS** and **APPEND TO EXISTING LOG FILE**.
4. Uncheck **DUMP SUMBOL TABLE**, **VISUAL NOTIFICATION**, **SOUND NOTIFICATION** and **CREATE CRASH DUMP FILE**.
5. Set the **NUMBER OF INSTRUCTIONS** to a suitable value to capture enough calls in the stacktrace. A value of at 25 should be enough.

Note that the file generated can be very large.

### 31.5.1.4. Debugging `mysqld` under `gdb`

On most systems you can also start `mysqld` from `gdb` to get more information if `mysqld` crashes.

With some older `gdb` versions on Linux you must use `run --one-thread` if you want to be able to debug `mysqld` threads. In this case, you can only have one thread active at a time. We recommend you to upgrade to `gdb 5.1` ASAP as thread debugging works much better with this version!

NPTL threads (the new thread library on Linux) may cause problems while running `mysqld` under `gdb`. Some symptoms are:

- `mysqld` hangs during startup (before it writes `ready for connections`).
- `mysqld` crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case, you should set the following environment variable in the shell before starting `gdb`:

```
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running `mysqld` under `gdb`, you should disable the stack trace with `--skip-stack-trace` to be able to catch segfaults within `gdb`.

In MySQL 4.0.14 and above you should use the `--gdb` option to `mysqld`. This installs an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling.

It's very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` doesn't free the memory for old threads. You can avoid this problem by starting `mysqld` with `thread_cache_size` set to a value equal to `max_connections + 1`. In most cases just using `--thread_cache_size=5` helps a lot!

If you want to get a core dump on Linux if `mysqld` dies with a `SIGSEGV` signal, you can start `mysqld` with the `--core-file`

option. This core file can be used to make a backtrace that may help you find out why `mysqld` died:

```
shell> gdb mysqld core
gdb> backtrace full
gdb> quit
```

See [Section B.1.4.2, “What to Do If MySQL Keeps Crashing”](#).

If you are using `gdb` 4.17.x or above on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop noprint
handle SIGUSR2 nostop noprint
handle SIGWAITING nostop noprint
handle SIGLWP nostop noprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop noprint
```

If you have problems debugging threads with `gdb`, you should download `gdb` 5.x and try this instead. The new `gdb` version has very improved thread handling!

Here is an example how to debug `mysqld`:

```
shell> gdb /usr/local/libexec/mysqld
gdb> run
...
backtrace full # Do this when mysqld crashes
```

Include the above output in a bug report, which you can file using the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

If `mysqld` hangs you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where `mysqld` has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl `DBI` interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

### 31.5.1.5. Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See [Section 5.2.2, “The Error Log”](#). To get a stack trace, you must not compile `mysqld` with the `-fomit-frame-pointer` option to `gcc`. See [Section 31.5.1.1, “Compiling MySQL for Debugging”](#).

If the error file contains something like the following:

```
mysqld got signal 11;
The manual section 'Debugging a MySQL server' tells you how to
use a stack trace and/or the core file to produce a readable
backtrace that may help in finding out why mysqld died
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...
stack range sanity check, ok, backtrace follows
0x40077552
0x81281a0
0x8128f47
0x8127be0
0x8127995
0x8104947
0x80ff28f
0x810131b
0x80ee4bc
0x80c3c91
0x80c6b43
0x80c1fd9
0x80c1686
```

you can find where `mysqld` died by doing the following:

1. Copy the preceding numbers to a file, for example `mysqld.stack`.
2. Make a symbol file for the `mysqld` server:

```
nm -n libexec/mysqld > /tmp/mysqld.sym
```

If you have not linked `mysqld` statically, use the following command:

```
nm -D -n libexec/mysqld > /tmp/mysqld.sym
```

If you want to decode C++ symbols, use the `--demangle`, if available, to `nm`. If your version of `nm` does not have this option, you will need to use the `c++filt` command after the stack dump has been produced to demangle the C++ names.

Note that most MySQL binary distributions (except for the "debug" packages, where this information is included inside of the binaries themselves) ship with the above file, named `mysqld.sym.gz`. In this case, you can simply unpack it by doing:

```
gunzip < bin/mysqld.sym.gz > /tmp/mysqld.sym
```

3. Execute the following line:

```
resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack
```

If you were not able to include demangled C++ names in your symbol file, use `c++filt` on the output:

```
resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack|c++filt
```

This prints out where `mysqld` died. If this doesn't help you find out why `mysqld` died, you should make a bug report and include the output from the above command with the bug report.

Note however that in most cases it does not help us to just have a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, we would in most cases need to know the query that killed `mysqld` and preferably a test case so that we can repeat the problem! See [Section 1.7, "How to Report Bugs or Problems"](#).

### 31.5.1.6. Using Server Logs to Find Causes of Errors in `mysqld`

Note that before starting `mysqld` with `--log` you should check all your tables with `myisamchk`. See [Chapter 5, MySQL Server Administration](#).

If `mysqld` dies or hangs, you should start `mysqld` with `--log`. When `mysqld` dies again, you can examine the end of the log file for the query that killed `mysqld`.

If you are using `--log` without a file name, the log is stored in the database directory as `host_name.log`. In most cases it is the last query in the log file that killed `mysqld`, but if possible you should verify this by restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that didn't complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See [Section 12.3.2, "EXPLAIN Syntax"](#).

You can find the queries that take a long time to execute by starting `mysqld` with `--log-slow-queries`. See [Section 5.2.5, "The Slow Query Log"](#).

If you find the text `mysqld restarted` in the error log file (normally named `hostname.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see [Chapter 5, MySQL Server Administration](#)), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this doesn't help and you can't find anything in the `mysql` mail archive, you should report the bug to a MySQL mailing list. The mailing lists are described at <http://lists.mysql.com/>, which also has links to online list archives.

If you have started `mysqld` with `--myisam-recover`, MySQL automatically checks and tries to repair `MyISAM` tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file `'Warning: Checking table ...'` which is followed by `Warning: Repairing table` if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See [Section 5.1.2, "Command Options"](#).

It is not a good sign if `mysqld` did die unexpectedly, but in this case, you should not investigate the `Checking table...` messages, but instead try to find out why `mysqld` died.

### 31.5.1.7. Making a Test Case If You Experience Table Corruption

If you get corrupted tables or if `mysqld` always fails after some update commands, you can test whether this bug is reproducible by doing the following:

- Take down the MySQL daemon (with `mysqladmin shutdown`).
- Make a backup of the tables (to guard against the very unlikely case that the repair does something bad).
- Check all tables with `myisamchk -s database/*.MYI`. Repair any wrong tables with `myisamchk -r database/table.MYI`.
- Make a second backup of the tables.
- Remove (or move away) any old log files from the MySQL data directory if you need more space.
- Start `mysqld` with `--log-bin`. See Section 5.2.4, “The Binary Log”. If you want to find a query that crashes `mysqld`, you should use `--log --log-bin`.
- When you have gotten a crashed table, stop the `mysqld` server.
- Restore the backup.
- Restart the `mysqld` server **without** `--log-bin`
- Re-execute the commands with `mysqlbinlog binary-log-file | mysql`. The binary log is saved in the MySQL database directory with the name `hostname-bin.#`.
- If the tables are corrupted again or you can get `mysqld` to die with the above command, you have found reproducible bug that should be easy to fix! FTP the tables and the binary log to <ftp://ftp.mysql.com/pub/mysql/upload/> and report it in our bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. (Please note that the `/pub/mysql/upload/` FTP directory is not listable, so you'll not see what you've uploaded in your FTP client.) If you are a support customer, you can use the MySQL Customer Support Center <https://support.mysql.com/> to alert the MySQL team about the problem and have it fixed as soon as possible.

You can also use the script `mysql_find_rows` to just execute some of the update statements if you want to narrow down the problem.

## 31.5.2. Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `--with-debug` or `--with-debug=full`. See Section 2.9.2, “Typical configure Options”.

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```
shell> MYSQL_DEBUG=d:t:O,/tmp/client.trace
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
shell> mysql --debug=d:t:O,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See Section 1.7, “How to Report Bugs or Problems”.

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

## 31.5.3. The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is debugging. See Section 31.5.1.2, “Creating Trace Files”.

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support. For more information about programming with the DBUG package, see the DBUG manual in the `debug` directory of MySQL source distributions. It's best to use a recent distribution to get the most updated DBUG manual.

You use the debug package by invoking a program with the `--debug="..."` or the `-#...` option.

Most MySQL programs have a default debug string that is used if you don't specify an option to `--debug`. The default trace file is

usually `/tmp/program_name.trace` on Unix and `\program_name.trace` on Windows.

The debug control string is a sequence of colon-separated fields as follows:

```
<field_1>:<field_2>:...:<field_N>
```

Each field consists of a mandatory flag character followed by an optional “,” and comma-separated list of modifiers:

```
flag[,modifier,modifier,...,modifier]
```

The currently recognized flag characters are:

Flag	Description
d	Enable output from <code>DEBUG_&lt;N&gt;</code> macros for the current state. May be followed by a list of keywords which selects output only for the <code>DEBUG</code> macros with that keyword. An empty list of keywords implies output for all macros.
D	Delay after each debugger output line. The argument is the number of tenths of seconds to delay, subject to machine capabilities. For example, <code>-#D,20</code> specifies a delay of two seconds.
f	Limit debugging, tracing, and profiling to the list of named functions. Note that a null list disables all functions. The appropriate <code>d</code> or <code>t</code> flags must still be given; this flag only limits their actions if they are enabled.
F	Identify the source file name for each line of debug or trace output.
i	Identify the process with the PID or thread ID for each line of debug or trace output.
g	Enable profiling. Create a file called <code>dbugmon.out</code> containing information that can be used to profile the program. May be followed by a list of keywords that select profiling only for the functions in that list. A null list implies that all functions are considered.
L	Identify the source file line number for each line of debug or trace output.
n	Print the current function nesting depth for each line of debug or trace output.
N	Number each line of debug output.
o	Redirect the debugger output stream to the specified file. The default output is <code>stderr</code> .
O	Like <code>o</code> , but the file is really flushed between each write. When needed, the file is closed and reopened between each write.
p	Limit debugger actions to specified processes. A process must be identified with the <code>DEBUG_PROCESS</code> macro and match one in the list for debugger actions to occur.
P	Print the current process name for each line of debug or trace output.
r	When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin.
S	Do function <code>_sanity(_file_,_line_)</code> at each debugged function until <code>_sanity()</code> returns something that differs from 0. (Mostly used with <code>safemalloc</code> to find memory leaks)
t	Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.

Some examples of debug control strings that might appear on a shell command line (the `-#` is typically used to introduce a control string to an application program) are:

```

-#d:t
-#d:f,main,subr1:F:L:t,20
-#d,input,output,files:n
-#d:t:i:0,\\mysql.trace

```

In MySQL, common tags to print (with the `d` option) are `enter`, `exit`, `error`, `warning`, `info`, and `loop`.

### 31.5.4. Comments about RTS Threads

I have tried to use the RTS thread packages with MySQL but stumbled on the following problems:

They use old versions of many POSIX calls and it is very tedious to make wrappers for all functions. I am inclined to think that it would be easier to change the thread libraries to the newest POSIX specification.

Some wrappers are currently written. See `mysys/my_pthread.c` for more info.

At least the following should be changed:

`pthread_get_specific` should use one argument. `sigwait` should take two arguments. A lot of functions (at least `pthread_cond_wait`, `pthread_cond_timedwait()`) should return the error code on error. Now they return `-1` and set

`errno`.

Another problem is that user-level threads use the `ALRM` signal and this aborts a lot of functions (`read`, `write`, `open`...). MySQL should do a retry on interrupt on all of these but it is not that easy to verify it.

The biggest unsolved problem is the following:

To get thread-level alarms I changed `mysys/thr_alarm.c` to wait between alarms with `pthread_cond_timedwait()`, but this aborts with error `EINTR`. I tried to debug the thread library as to why this happens, but couldn't find any easy solution.

If someone wants to try MySQL with RTS threads I suggest the following:

- Change functions MySQL uses from the thread library to POSIX. This shouldn't take that long.
- Compile all libraries with the `-DHAVE_rts_threads`.
- Compile `thr_alarm`.
- If there are some small differences in the implementation, they may be fixed by changing `my_pthread.h` and `my_pthread.c`.
- Run `thr_alarm`. If it runs without any “warning,” “error,” or aborted messages, you are on the right track. Here is a successful run on Solaris:

```

Main thread: 1
Thread 0 (5) started
Thread: 5 Waiting
process_alarm
Thread 1 (6) started
Thread: 6 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 1 (1) sec
Thread: 6 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 2 (2) sec
Thread: 6 Simulation of no alarm needed
Thread: 6 Slept for 0 (3) sec
Thread: 6 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 4 (4) sec
Thread: 6 Waiting
process_alarm
thread_alarm
Thread: 5 Slept for 10 (10) sec
Thread: 5 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 5 (5) sec
Thread: 6 Waiting
process_alarm
process_alarm
...
thread_alarm
Thread: 5 Slept for 0 (1) sec
end

```

### 31.5.5. Differences Between Thread Packages

MySQL is very dependent on the thread package used. So when choosing a good platform for MySQL, the thread package is very important.

There are at least three types of thread packages:

- User threads in a single process. Thread switching is managed with alarms and the threads library manages all non-thread-safe functions with locks. Read, write and select operations are usually managed with a thread-specific select that switches to another thread if the running threads have to wait for data. If the user thread packages are integrated in the standard libs (FreeBSD and BSDI threads) the thread package requires less overhead than thread packages that have to map all unsafe calls (MIT-pthreads, FSU Pthreads and RTS threads). In some environments (for example, SCO), all system calls are thread-safe so the mapping can be done very easily (FSU Pthreads on SCO). Downside: All mapped calls take a little time and it's quite tricky to be able to handle all situations. There are usually also some system calls that are not handled by the thread package (like

MIT-pthreads and sockets). Thread scheduling isn't always optimal.

- User threads in separate processes. Thread switching is done by the kernel and all data are shared between threads. The thread package manages the standard thread calls to allow sharing data between threads. LinuxThreads is using this method. Downside: Lots of processes. Thread creating is slow. If one thread dies the rest are usually left hanging and you must kill them all before restarting. Thread switching is somewhat expensive.
- Kernel threads. Thread switching is handled by the thread library or the kernel and is very fast. Everything is done in one process, but on some systems, `ps` may show the different threads. If one thread aborts, the whole process aborts. Most system calls are thread-safe and should require very little overhead. Solaris, HP-UX, AIX and OSF/1 have kernel threads.

In some systems kernel threads are managed by integrating user level threads in the system libraries. In such cases, the thread switching can only be done by the thread library and the kernel isn't really "thread aware."

---

# Appendix A. MySQL 5.1 Frequently Asked Questions

## A.1. MySQL 5.1 FAQ — General

### Questions

- [33.1.1](#): Which version of MySQL is production-ready (GA)?
- [33.1.2](#): Can MySQL 5.1 do subqueries?
- [33.1.3](#): Can MySQL 5.1 perform multiple-table inserts, updates, and deletes?
- [33.1.4](#): Does MySQL 5.1 have a Query Cache? Does it work on Server, Instance or Database?
- [33.1.5](#): Does MySQL 5.1 have Sequences?
- [33.1.6](#): Does MySQL 5.1 have a `NOW( )` function with fractions of seconds?
- [33.1.7](#): Does MySQL 5.1 work with multi-core processors?
- [33.1.8](#): Is there a hot backup tool for MyISAM like InnoDB Hot Backup?
- [33.1.9](#): Have there been any improvements in error reporting when foreign keys fail? Does MySQL now report which column and reference failed?
- [33.1.10](#): Can MySQL 5.1 perform ACID transactions?

### Questions and Answers

#### 33.1.1: Which version of MySQL is production-ready (GA)?

MySQL 5.0 became Generally Available (GA) with MySQL 5.0.15, which was released for production use on 19 October 2005. We are now working on MySQL 5.1, which is currently a Release Candidate. Development work on MySQL 6.0 has started; currently, MySQL 6.0 is in alpha status.

#### 33.1.2: Can MySQL 5.1 do subqueries?

Yes. See [Section 12.2.8](#), “Subquery Syntax”.

#### 33.1.3: Can MySQL 5.1 perform multiple-table inserts, updates, and deletes?

Yes. For the syntax required to perform multiple-table updates, see [Section 12.2.10](#), “UPDATE Syntax”; for that required to perform multiple-table deletes, see [Section 12.2.1](#), “DELETE Syntax”.

A multiple-table insert can be accomplished using a trigger whose `FOR EACH ROW` clause contains multiple `INSERT` statements within a `BEGIN . . . END` block. See [Section 23.3](#), “Using Triggers”.

#### 33.1.4: Does MySQL 5.1 have a Query Cache? Does it work on Server, Instance or Database?

Yes. The query cache operates on the server level, caching complete result sets matched with the original query string. If an exactly identical query is made (which often happens, particularly in web applications), no parsing or execution is necessary; the result is sent directly from the cache. Various tuning options are available. See [Section 7.5.4](#), “The MySQL Query Cache”.

#### 33.1.5: Does MySQL 5.1 have Sequences?

No. However, MySQL has an `AUTO_INCREMENT` system, which in MySQL 5.1 can also handle inserts in a multi-master replication setup. With the `--auto-increment-increment` and `--auto-increment-offset` startup options, you can set each server to generate auto-increment values that don't conflict with other servers. The `--auto-increment-increment` value should be greater than the number of servers, and each server should have a unique offset.

#### 33.1.6: Does MySQL 5.1 have a `NOW( )` function with fractions of seconds?

No. This is on the MySQL roadmap as a “rolling feature”. This means that it is not a flagship feature, but will be implemented, development time permitting. Specific customer demand may change this scheduling.

However, MySQL does parse time strings with a fractional component. See [Section 10.3.2](#), “The TIME Type”.

#### 33.1.7: Does MySQL 5.1 work with multi-core processors?

Yes. MySQL is fully multi-threaded, and will make use of multiple CPUs, provided that the operating system supports them.

### 33.1.8: Is there a hot backup tool for MyISAM like InnoDB Hot Backup?

This is currently under development for a future MySQL release.

### 33.1.9: Have there been there any improvements in error reporting when foreign keys fail? Does MySQL now report which column and reference failed?

The foreign key support in `InnoDB` has seen improvements in each major version of MySQL. Foreign key support generic to all storage engines is scheduled for MySQL 6.x; this should resolve any inadequacies in the current storage engine specific implementation.

### 33.1.10: Can MySQL 5.1 perform ACID transactions?

Yes. All current MySQL versions support transactions. The `InnoDB` storage engine offers full ACID transactions with row-level locking, multi-versioning, non-locking repeatable reads, and all four SQL standard isolation levels.

The `NDB` storage engine supports the `READ COMMITTED` transaction isolation level only.

## A.2. MySQL 5.1 FAQ — Storage Engines

### Questions

- [33.2.1](#): Where can I obtain complete documentation for MySQL storage engines and the pluggable storage engine architecture?
- [33.2.2](#): Are there any new storage engines in MySQL 5.1?
- [33.2.3](#): Have any storage engines been removed in MySQL 5.1?
- [33.2.4](#): What are the unique benefits of the `ARCHIVE` storage engine?
- [33.2.5](#): Do the new features in MySQL 5.1 apply to all storage engines?

### Questions and Answers

#### 33.2.1: Where can I obtain complete documentation for MySQL storage engines and the pluggable storage engine architecture?

See [Chapter 13, Storage Engines](#). That chapter contains information about all MySQL storage engines except for the `NDB` storage engine used for MySQL Cluster; `NDB` is covered in [Chapter 19, MySQL Cluster](#).

#### MySQL Enterprise

For expert advice about the storage engine(s) most suitable to your circumstances subscribe to the MySQL Enterprise Monitor. For more information, see <http://www.mysql.com/products/enterprise/advisors.html>.

#### 33.2.2: Are there any new storage engines in MySQL 5.1?

No. There have been significant improvements in existing storage engines, in particular for the `NDB` storage engine that forms the basis for MySQL Cluster.

The Falcon storage engine is available in MySQL 6.0. See [MySQL 6.0 Reference Manual](#).

#### 33.2.3: Have any storage engines been removed in MySQL 5.1?

Yes. MySQL 5.1 no longer supports the `BDB` storage engine. Any existing `BDB` tables should be converted to another storage engine before upgrading to MySQL 5.1.

#### 33.2.4: What are the unique benefits of the `ARCHIVE` storage engine?

The `ARCHIVE` storage engine is ideally suited for storing large amounts of data without indexes; it has a very small footprint, and performs selects using table scans. See [Section 13.10, “The ARCHIVE Storage Engine”](#), for details.

#### 33.2.5: Do the new features in MySQL 5.1 apply to all storage engines?

The general new features such as views, stored procedures, triggers, `INFORMATION_SCHEMA`, precision math (`DECIMAL` column type), and the `BIT` column type, apply to all storage engines. There are also additions and changes for specific storage engines.

## A.3. MySQL 5.1 FAQ — Server SQL Mode

### Questions

- [33.3.1](#): What are server SQL modes?
- [33.3.2](#): How many server SQL modes are there?
- [33.3.3](#): How do you determine the server SQL mode?
- [33.3.4](#): Is the mode dependent on the database or connection?
- [33.3.5](#): Can the rules for strict mode be extended?
- [33.3.6](#): Does strict mode impact performance?
- [33.3.7](#): What is the default server SQL mode when My SQL 5.1 is installed?

### Questions and Answers

#### 33.3.1: What are server SQL modes?

Server SQL modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers. The MySQL Server apply these modes individually to different clients. For more information, see [Section 5.1.7, “SQL Modes”](#).

#### 33.3.2: How many server SQL modes are there?

Each mode can be independently switched on and off. See [Section 5.1.7, “SQL Modes”](#), for a complete list of available modes.

#### 33.3.3: How do you determine the server SQL mode?

You can set the default SQL mode (for `mysqld` startup) with the `--sql-mode` option. Using the statement `SET [SESSION|GLOBAL] sql_mode='modes'`, you can change the settings from within a connection, either locally to the connection, or to take effect globally. You can retrieve the current mode by issuing a `SELECT @@sql_mode` statement.

#### 33.3.4: Is the mode dependent on the database or connection?

A mode is not linked to a particular database. Modes can be set locally to the session (connection), or globally for the server. you can change these settings using `SET [SESSION|GLOBAL] sql_mode='modes'`.

#### 33.3.5: Can the rules for strict mode be extended?

When we refer to *strict mode*, we mean a mode where at least one of the modes `TRADITIONAL`, `STRICT_TRANS_TABLES`, or `STRICT_ALL_TABLES` is enabled. Options can be combined, so you can add additional restrictions to a mode. See [Section 5.1.7, “SQL Modes”](#), for more information.

#### 33.3.6: Does strict mode impact performance?

The intensive validation of input data that some settings requires more time than if the validation is not done. While the performance impact is not that great, if you do not require such validation (perhaps your application already handles all of this), then MySQL gives you the option of leaving strict mode disabled. However — if you do require it — strict mode can provide such validation.

#### 33.3.7: What is the default server SQL mode when My SQL 5.1 is installed?

By default, no special modes are enabled. See [Section 5.1.7, “SQL Modes”](#), for information about all available modes and MySQL's default behavior.

## A.4. MySQL 5.1 FAQ — Stored Procedures

### Questions

- [33.4.1](#): Does MySQL 5.1 support stored procedures?
- [33.4.2](#): Where can I find documentation for MySQL stored procedures and stored functions?
- [33.4.3](#): Is there a discussion forum for MySQL stored procedures?

- [33.4.4](#): Where can I find the ANSI SQL 2003 specification for stored procedures?
- [33.4.5](#): How do you manage stored routines?
- [33.4.6](#): Is there a way to view all stored procedures and stored functions in a given database?
- [33.4.7](#): Where are stored procedures stored?
- [33.4.8](#): Is it possible to group stored procedures or stored functions into packages?
- [33.4.9](#): Can a stored procedure call another stored procedure?
- [33.4.10](#): Can a stored procedure call a trigger?
- [33.4.11](#): Can a stored procedure access tables?
- [33.4.12](#): Do stored procedures have a statement for raising application errors?
- [33.4.13](#): Do stored procedures provide exception handling?
- [33.4.14](#): Can MySQL 5.1 stored routines return result sets?
- [33.4.15](#): Is `WITH RECOMPILE` supported for stored procedures?
- [33.4.16](#): Is there a MySQL equivalent to using `mod_plsql` as a gateway on Apache to talk directly to a stored procedure in the database?
- [33.4.17](#): Can I pass an array as input to a stored procedure?
- [33.4.18](#): Can I pass a cursor as an `IN` parameter to a stored procedure?
- [33.4.19](#): Can I return a cursor as an `OUT` parameter from a stored procedure?
- [33.4.20](#): Can I print out a variable's value within a stored routine for debugging purposes?
- [33.4.21](#): Can I commit or roll back transactions inside a stored procedure?
- [33.4.22](#): Do MySQL 5.1 stored procedures and functions work with replication?
- [33.4.23](#): Are stored procedures and functions created on a master server replicated to a slave?
- [33.4.24](#): How are actions that take place inside stored procedures and functions replicated?
- [33.4.25](#): Are there special security requirements for using stored procedures and functions together with replication?
- [33.4.26](#): What limitations exist for replicating stored procedure and function actions?
- [33.4.27](#): Do the preceding limitations affect MySQL's ability to do point-in-time recovery?
- [33.4.28](#): What is being done to correct the aforementioned limitations?

### Questions and Answers

#### **33.4.1: Does MySQL 5.1 support stored procedures?**

Yes. MySQL 5.1 supports two types of stored routines — stored procedures and stored functions.

#### **33.4.2: Where can I find documentation for MySQL stored procedures and stored functions?**

See [Chapter 22, \*Stored Procedures and Functions\*](#).

#### **33.4.3: Is there a discussion forum for MySQL stored procedures?**

Yes. See <http://forums.mysql.com/list.php?98>.

#### **33.4.4: Where can I find the ANSI SQL 2003 specification for stored procedures?**

Unfortunately, the official specifications are not freely available (ANSI makes them available for purchase). However, there are books — such as *SQL-99 Complete, Really* by Peter Gulutzan and Trudy Pelzer — which give a comprehensive overview of the standard, including coverage of stored procedures.

**33.4.5: How do you manage stored routines?**

It is always good practice to use a clear naming scheme for your stored routines. You can manage stored procedures with `CREATE [FUNCTION|PROCEDURE]`, `ALTER [FUNCTION|PROCEDURE]`, `DROP [FUNCTION|PROCEDURE]`, and `SHOW CREATE [FUNCTION|PROCEDURE]`. You can obtain information about existing stored procedures using the `ROUTINES` table in the `INFORMATION_SCHEMA` database (see [Section 26.14, “The INFORMATION\\_SCHEMA ROUTINES Table”](#)).

**33.4.6: Is there a way to view all stored procedures and stored functions in a given database?**

Yes. For a database named `dbname`, use this query on the `INFORMATION_SCHEMA.ROUTINES` table:

```
SELECT ROUTINE_TYPE, ROUTINE_NAME
FROM INFORMATION_SCHEMA.ROUTINES
WHERE ROUTINE_SCHEMA='dbname';
```

For more information, see [Section 26.14, “The INFORMATION\\_SCHEMA ROUTINES Table”](#).

The body of a stored routine can be viewed using `SHOW CREATE FUNCTION` (for a stored function) or `SHOW CREATE PROCEDURE` (for a stored procedure). See [Section 12.5.4.8, “SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION Syntax”](#), for more information.

**33.4.7: Where are stored procedures stored?**

In the `proc` table of the `mysql` system database. However, you should not access the tables in the system database directly. Instead, use `SHOW CREATE FUNCTION` to obtain information about stored functions, and `SHOW CREATE PROCEDURE` to obtain information about stored procedures. See [Section 12.5.4.8, “SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION Syntax”](#), for more information about these statements.

You can also query the `ROUTINES` table in the `INFORMATION_SCHEMA` database — see [Section 26.14, “The INFORMATION\\_SCHEMA ROUTINES Table”](#), for information about this table.

**33.4.8: Is it possible to group stored procedures or stored functions into packages?**

No. This is not supported in MySQL 5.1.

**33.4.9: Can a stored procedure call another stored procedure?**

Yes.

**33.4.10: Can a stored procedure call a trigger?**

A stored procedure can execute an SQL statement, such as an `UPDATE`, that causes a trigger to activate.

**33.4.11: Can a stored procedure access tables?**

Yes. A stored procedure can access one or more tables as required.

**33.4.12: Do stored procedures have a statement for raising application errors?**

Not in MySQL 5.1. We intend to implement the SQL standard `SIGNAL` and `RESIGNAL` statements in a future MySQL release.

**33.4.13: Do stored procedures provide exception handling?**

MySQL implements `HANDLER` definitions according to the SQL standard. See [Section 22.2.8.2, “DECLARE Handlers”](#), for details.

**33.4.14: Can MySQL 5.1 stored routines return result sets?**

*Stored procedures* can, but stored functions cannot. If you perform an ordinary `SELECT` inside a stored procedure, the result set is returned directly to the client. You need to use the MySQL 4.1 (or above) client-server protocol for this to work. This means that — for instance — in PHP, you need to use the `mysqli` extension rather than the old `mysql` extension.

**33.4.15: Is `WITH RECOMPILE` supported for stored procedures?**

Not in MySQL 5.1.

**33.4.16: Is there a MySQL equivalent to using `mod_plsql` as a gateway on Apache to talk directly to a stored procedure in the database?**

There is no equivalent in MySQL 5.1.

**33.4.17: Can I pass an array as input to a stored procedure?**

Not in MySQL 5.1.

**33.4.18: Can I pass a cursor as an `IN` parameter to a stored procedure?**

In MySQL 5.1, cursors are available inside stored procedures only.

**33.4.19: Can I return a cursor as an `OUT` parameter from a stored procedure?**

In MySQL 5.1, cursors are available inside stored procedures only. However, if you do not open a cursor on a `SELECT`, the result will be sent directly to the client. You can also `SELECT INTO` variables. See [Section 12.2.7, “SELECT Syntax”](#).

**33.4.20: Can I print out a variable's value within a stored routine for debugging purposes?**

Yes, you can do this in a *stored procedure*, but not in a stored function. If you perform an ordinary `SELECT` inside a stored procedure, the result set is returned directly to the client. You will need to use the MySQL 4.1 (or above) client-server protocol for this to work. This means that — for instance — in PHP, you need to use the `mysqli` extension rather than the old `mysql` extension.

**33.4.21: Can I commit or roll back transactions inside a stored procedure?**

Yes. However, you cannot perform transactional operations within a stored function.

**33.4.22: Do MySQL 5.1 stored procedures and functions work with replication?**

Yes, standard actions carried out in stored procedures and functions are replicated from a master MySQL server to a slave server. There are a few limitations that are described in detail in [Section 22.4, “Binary Logging of Stored Routines and Triggers”](#).

**33.4.23: Are stored procedures and functions created on a master server replicated to a slave?**

Yes, creation of stored procedures and functions carried out through normal DDL statements on a master server are replicated to a slave, so the objects will exist on both servers. `ALTER` and `DROP` statements for stored procedures and functions are also replicated.

**33.4.24: How are actions that take place inside stored procedures and functions replicated?**

MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a slave server. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

**33.4.25: Are there special security requirements for using stored procedures and functions together with replication?**

Yes. Because a slave server has authority to execute any statement read from a master's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

1. Any user wishing to create stored functions must be granted the `SUPER` privilege.
2. Alternatively, a DBA can set the `log_bin_trust_function_creators` system variable to 1, which enables anyone with the standard `CREATE ROUTINE` privilege to create stored functions.

**33.4.26: What limitations exist for replicating stored procedure and function actions?**

Non-deterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly reproduced, and therefore, random actions replicated to a slave will not mirror those performed on a master. Note that declaring stored functions to be `DETERMINISTIC` or setting the `log_bin_trust_function_creators` system variable to 0 will not allow random-valued operations to be invoked.

In addition, time-based actions cannot be reproduced on a slave because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, non-transactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a master may be partially updated from DML activity, but no updates are done to the slave because of the errors that occurred. A workaround is for a function's DML actions to be carried out with the `IGNORE` keyword so that updates on the master that cause errors are ignored and updates that do not cause errors are replicated to the slave.

**33.4.27: Do the preceding limitations affect MySQL's ability to do point-in-time recovery?**

The same limitations that affect replication do affect point-in-time recovery.

**33.4.28: What is being done to correct the aforementioned limitations?**

As of MySQL 5.1.5, you can choose either statement-based replication or row-based replication. The original replication implementation is based on statement-based binary logging. Row-based binary logging resolves the limitations mentioned earlier.

Beginning with MySQL 5.1.8, *mixed* replication is also available (by starting the server with `--binlog-format=mixed`). This hybrid, “smart” form of replication “knows” whether statement-level replication can safely be used, or row-level replication is required.

For additional information, see [Section 18.1.2, “Replication Formats”](#).

## A.5. MySQL 5.1 FAQ — Triggers

### Questions

- [33.5.1](#): Where can I find the documentation for MySQL 5.1 triggers?
- [33.5.2](#): Is there a discussion forum for MySQL Triggers?
- [33.5.3](#): Does MySQL 5.1 have statement-level or row-level triggers?
- [33.5.4](#): Are there any default triggers?
- [33.5.5](#): How are triggers managed in MySQL?
- [33.5.6](#): Is there a way to view all triggers in a given database?
- [33.5.7](#): Where are triggers stored?
- [33.5.8](#): Can a trigger call a stored procedure?
- [33.5.9](#): Can triggers access tables?
- [33.5.10](#): Can triggers call an external application through a UDF?
- [33.5.11](#): Is possible for a trigger to update tables on a remote server?
- [33.5.12](#): Do triggers work with replication?
- [33.5.13](#): How are actions carried out through triggers on a master replicated to a slave?

### Questions and Answers

#### **33.5.1: Where can I find the documentation for MySQL 5.1 triggers?**

See [Chapter 23, \*Triggers\*](#).

#### **33.5.2: Is there a discussion forum for MySQL Triggers?**

Yes. It is available at <http://forums.mysql.com/list.php?99>.

#### **33.5.3: Does MySQL 5.1 have statement-level or row-level triggers?**

In MySQL 5.1, all triggers are `FOR EACH ROW` — that is, the trigger is activated for each row that is inserted, updated, or deleted. MySQL 5.1 does not support triggers using `FOR EACH STATEMENT`.

#### **33.5.4: Are there any default triggers?**

Not explicitly. MySQL does have specific special behavior for some `TIMESTAMP` columns, as well as for columns which are defined using `AUTO_INCREMENT`.

#### **33.5.5: How are triggers managed in MySQL?**

In MySQL 5.1, triggers can be created using the `CREATE TRIGGER` statement, and dropped using `DROP TRIGGER`. See [Section 23.1, “CREATE TRIGGER Syntax”](#), and [Section 23.2, “DROP TRIGGER Syntax”](#), for more about these statements.

Information about triggers can be obtained by querying the `INFORMATION_SCHEMA.TRIGGERS` table. See [Section 26.16, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

#### **33.5.6: Is there a way to view all triggers in a given database?**

Yes. You can obtain a listing of all triggers defined on database `dbname` using a query on the `INFORMATION_SCHEMA.TRIGGERS` table such as the one shown here:

```
SELECT TRIGGER_NAME, EVENT_MANIPULATION, EVENT_OBJECT_TABLE, ACTION_STATEMENT
FROM INFORMATION_SCHEMA.TRIGGERS
WHERE TRIGGER_SCHEMA='dbname';
```

For more information about this table, see [Section 26.16, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

You can also use the `SHOW TRIGGERS` statement, which is specific to MySQL. See [Section 12.5.4.30, “SHOW TRIGGERS Syntax”](#).

### 33.5.7: Where are triggers stored?

Triggers for a table are currently stored in `.TRG` files, with one such file one per table.

### 33.5.8: Can a trigger call a stored procedure?

Yes.

### 33.5.9: Can triggers access tables?

A trigger can access both old and new data in its own table. Through a stored procedure, or a multiple-table update or delete statement, a trigger can also affect other tables.

### 33.5.10: Can triggers call an external application through a UDF?

No, not at present.

### 33.5.11: Is possible for a trigger to update tables on a remote server?

Yes. A table on a remote server could be updated using the `FEDERATED` storage engine. (See [Section 13.9, “The FEDERATED Storage Engine”](#)).

### 33.5.12: Do triggers work with replication?

Triggers and replication in MySQL 5.1 work in the same way as in most other database systems: Actions carried out through triggers on a master are not replicated to a slave server. Instead, triggers that exist on tables that reside on a MySQL master server need to be created on the corresponding tables on any MySQL slave servers so that the triggers activate on the slaves as well as the master.

### 33.5.13: How are actions carried out through triggers on a master replicated to a slave?

First, the triggers that exist on a master must be re-created on the slave server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table `EMP` that has an `AFTER` insert trigger, which exists on a master MySQL server. The same `EMP` table and `AFTER` insert trigger exist on the slave server as well. The replication flow would be:

1. An `INSERT` statement is made to `EMP`.
2. The `AFTER` trigger on `EMP` activates.
3. The `INSERT` statement is written to the binary log.
4. The replication slave picks up the `INSERT` statement to `EMP` and executes it.
5. The `AFTER` trigger on `EMP` that exists on the slave activates.

## A.6. MySQL 5.1 FAQ — Views

### Questions

- [33.6.1](#): Where can I find documentation covering MySQL Views?
- [33.6.2](#): Is there a discussion forum for MySQL Views?
- [33.6.3](#): What happens to a view if an underlying table is dropped or renamed?

- [33.6.4](#): Does MySQL 5.1 have table snapshots?
- [33.6.5](#): Does MySQL 5.1 have materialized views?
- [33.6.6](#): Can you insert into views that are based on joins?

### Questions and Answers

#### **33.6.1: Where can I find documentation covering MySQL Views?**

See [Chapter 25, Views](#).

#### **33.6.2: Is there a discussion forum for MySQL Views?**

Yes. See <http://forums.mysql.com/list.php?100>

#### **33.6.3: What happens to a view if an underlying table is dropped or renamed?**

After a view has been created, it is possible to drop or alter a table or view to which the definition refers. To check a view definition for problems of this kind, use the `CHECK TABLE` statement. (See [Section 12.5.2.3, “CHECK TABLE Syntax”](#).)

#### **33.6.4: Does MySQL 5.1 have table snapshots?**

No.

#### **33.6.5: Does MySQL 5.1 have materialized views?**

No.

#### **33.6.6: Can you insert into views that are based on joins?**

It is possible, provided that your `INSERT` statement has a column list that makes it clear there's only one table involved.

You *cannot* insert into multiple tables with a single insert on a view.

## A.7. MySQL 5.0 FAQ — [INFORMATION\\_SCHEMA](#)

### Questions

- [33.7.1](#): Where can I find documentation for the MySQL `INFORMATION_SCHEMA` database?
- [33.7.2](#): Is there a discussion forum for `INFORMATION_SCHEMA`?
- [33.7.3](#): Where can I find the ANSI SQL 2003 specification for `INFORMATION_SCHEMA`?
- [33.7.4](#): What is the difference between the Oracle Data Dictionary and MySQL's `INFORMATION_SCHEMA`?
- [33.7.5](#): Can I add to or otherwise modify the tables found in the `INFORMATION_SCHEMA` database?

### Questions and Answers

#### **33.7.1: Where can I find documentation for the MySQL `INFORMATION_SCHEMA` database?**

See [Chapter 26, `INFORMATION\_SCHEMA` Tables](#)

#### **33.7.2: Is there a discussion forum for `INFORMATION_SCHEMA`?**

See <http://forums.mysql.com/list.php?101>.

#### **33.7.3: Where can I find the ANSI SQL 2003 specification for `INFORMATION_SCHEMA`?**

Unfortunately, the official specifications are not freely available. (ANSI makes them available for purchase.) However, there are books available — such as *SQL-99 Complete, Really* by Peter Gultzan and Trudy Pelzer — which give a comprehensive overview of the standard, including `INFORMATION_SCHEMA`.

#### **33.7.4: What is the difference between the Oracle Data Dictionary and MySQL's `INFORMATION_SCHEMA`?**

Both Oracle and MySQL provide metadata in tables. However, Oracle and MySQL use different table names and column names.

MySQL's implementation is more similar to those found in DB2 and SQL Server, which also support `INFORMATION_SCHEMA` as defined in the SQL standard.

**33.7.5: Can I add to or otherwise modify the tables found in the `INFORMATION_SCHEMA` database?**

No. Since applications may rely on a certain standard structure, this should not be modified. For this reason, *MySQL AB cannot support bugs or other issues which result from modifying `INFORMATION_SCHEMA` tables or data.*

## A.8. MySQL 5.1 FAQ — Migration

### Questions

- [33.8.1](#): Where can I find information on how to migrate from MySQL 5.0 to MySQL 5.1?
- [33.8.2](#): How has storage engine (table type) support changed in MySQL 5.1 from previous versions?

### Questions and Answers

**33.8.1: Where can I find information on how to migrate from MySQL 5.0 to MySQL 5.1?**
